

Learning the Linux Command Line

A beginners guide

First Edition

MARTIN PETRAUSKAS

Northeastern University
Khoury College of Computer and Information Sciences

How To Use This Guide

This guide is for anyone who wants to learn the Linux operating system and the Bash command line. Throughout the guide, there are examples of how to use various bash commands. The chapters cover particular topics ranging from manipulating files and directories to connecting to remote servers.

Each chapter has basic definitions, examples, and a command summary that contains information about the specific topic. Furthermore, in each chapter, commands are printed in **bold**, files, filepaths, and command syntaxes are in *this font*, and examples that could be typed in the command line are in *italics*. The command summary at the end of each section contains a brief overview of the new commands introduced in that chapter.

If there is trouble running the examples given in this guide, it could be one of the following issues. First, a file might not be present. Some commands, such as filtering commands, require a particular file as input. Second, the syntax for the command could be incorrect. Commands are sensitive and some require additional arguments to run properly. Double check to ensure that all the necessary arguments are present and that nothing is mistyped.

Acknowledgments

There are a great number of people who helped collaborate on this guide. I would first like to thank Professor Christo Wilson for his support of the project. I came to Christo in mid-2018 with the idea of writing this guide. He supported the project from the beginning and he assisted with formulating some of the examples that are seen in the guide and making sure all the relevant information is covered.

I would also like to thank Samir Elhelw, Walter Geanacopoulos, Matthew Kline, and Garrett Tucker for reviewing this guide. And lastly, I would like to thank my father, Bruno Petrauskas, for proofreading and editing this guide from the very beginning.

Chapter 1

The Virtual Machine

Learning to use the Linux operating system requires the proper software and a Linux distribution. The examples in this guide use the Ubuntu operating system on a virtual machine (VM) which can be installed on the VMWare Workstation Player or the Oracle VM VirtualBox virtualization software. Either program will allow for the creation of a VM.

STEP 1: Acquire a Linux Operating System

Download the Ubuntu OS. The current version is Ubuntu 18.04.3 LTS, and it can be downloaded from the official Ubuntu website: <https://www.ubuntu.com/download/desktop>. The download file is large, approximately 1.8GB, so downloading the file can take some time.

STEP 2: Acquire the Virtual Machine Software

Download the necessary virtualization software to create a virtual machine with Ubuntu. The VMWare Workstation Player can be downloaded from the VMWare website: <https://www.vmware.com/products/workstation-player.html>. The Oracle VM VirtualBox can be downloaded from the VirtualBox website: <https://www.virtualbox.org/wiki/Downloads>. Once the download is complete, install the virtualization software on your computer before proceeding.

Chapter 2 covers the creation of a VM using VMWare and Chapter 3 cover the creation of a VM using VirtualBox. Go through the steps of one of these chapters to create the VM that can be used to learn the Linux operating system.

Chapter 2

Creating a VM with VMWare Workstation

This chapter steps you through the process of creating a VM using the VMWare Workstation software.

STEP 3: Create a New Virtual Machine

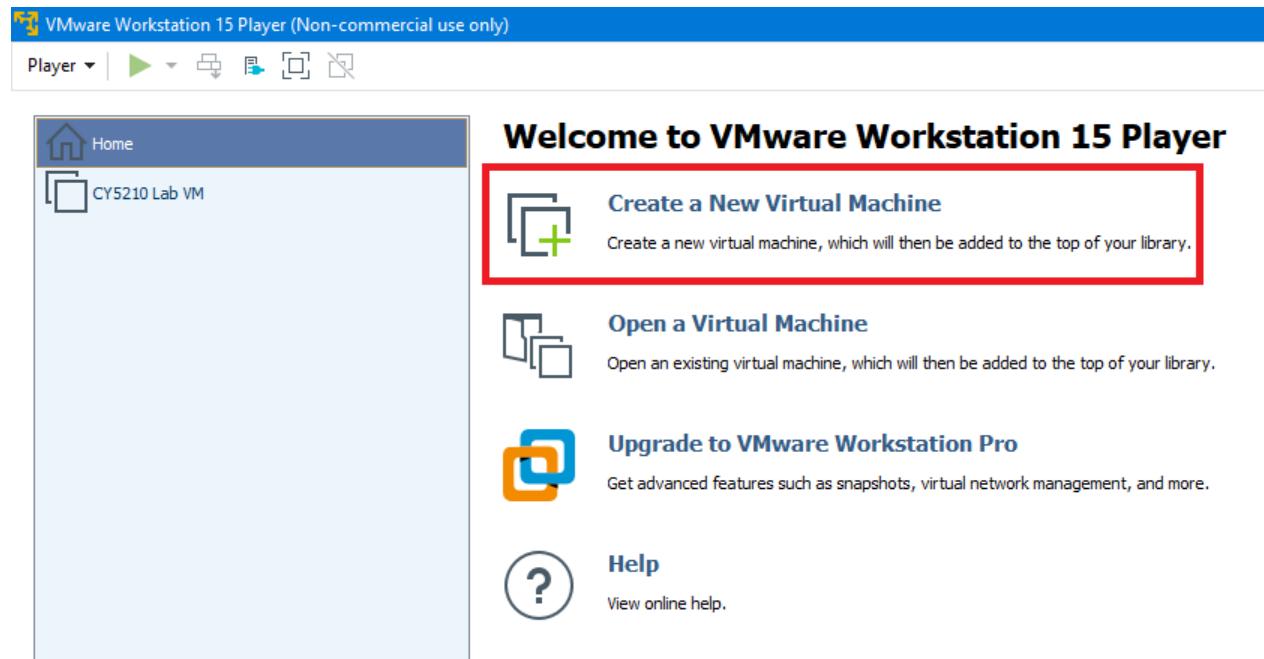

Figure 2.1: Creating a New VM with VMWare

Start the VMWare Workstation program. On the home screen, locate the area marked “Create a New Virtual Machine“ and click on it like in Figure 2.1

STEP 4: Selecting the Operating System

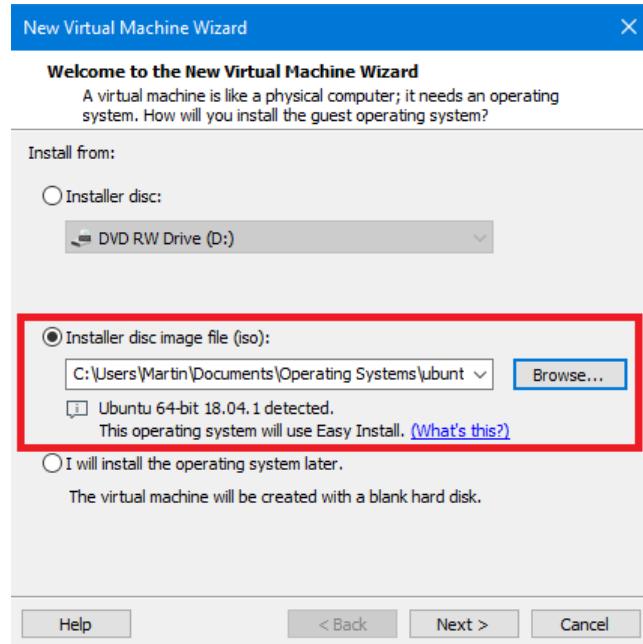

Figure 2.2: Selecting the Operating System

A pop-up will appear asking which how to install the operating system. Select the “Installer disc image file” option as noted in Figure 2.2 and browse for the Ubuntu ISO file that was downloaded in Chapter 1.

STEP 5: User Credentials

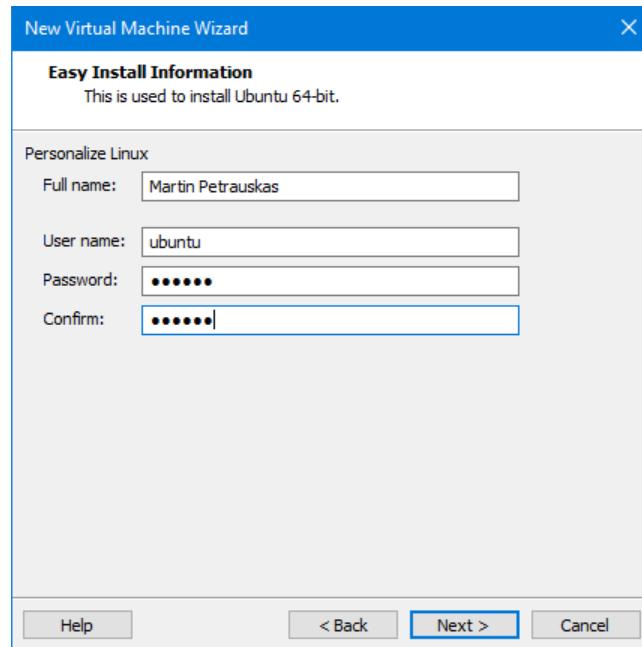

Figure 2.3: Inputting User Credentials for Ubuntu OS

The next pop up, like in Figure 2.3 will ask for user credentials which will be used for the Ubuntu operating system when it is created. Enter the username you would like to be used and a password as well.

STEP 6: Naming the Virtual Machine

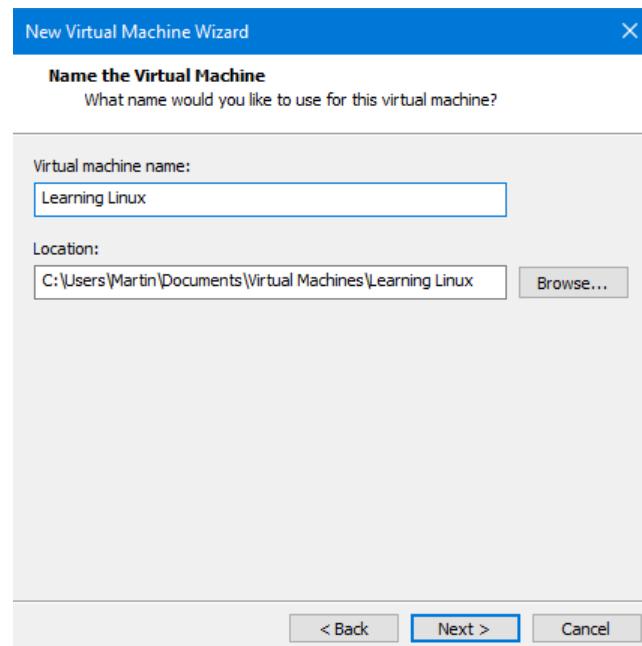

Figure 2.4: Naming the Virtual Machine

As in Figure 2.4, give your VM a simple yet memorable name. Additionally, if you wish, the location of where the VM is stored can be changed and it can be done at this step.

STEP 7: Selecting Virtual Disk Size

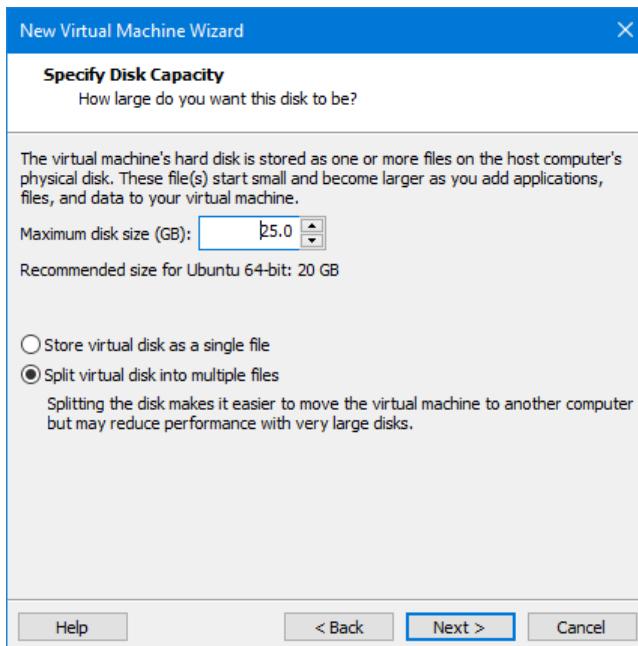

Figure 2.5: Selecting Disk Size

As in Figure 2.5, select the amount of space to be allocated to the virtual disk. For the examples in this book, 25GB is a good capacity.

STEP 8: Customize Hardware

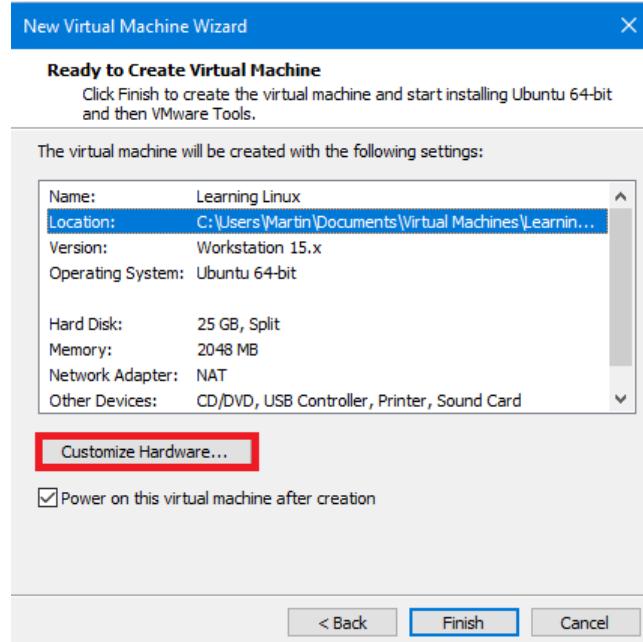

Figure 2.6: Customizing the Hardware

As in Figure 2.6, navigate to the “Customize Hardware” button and click it. You will be brought to a pop-up with more information.

STEP 9: Increase VM RAM

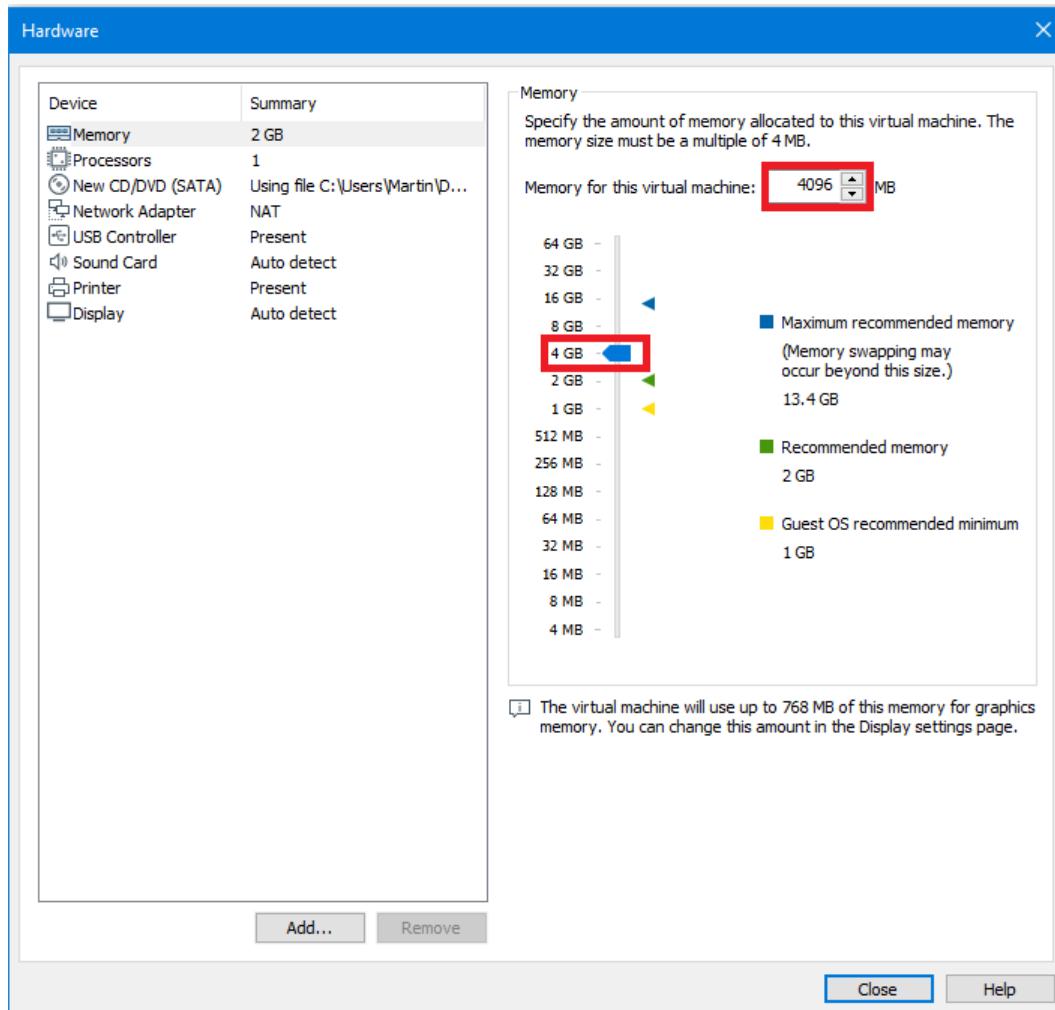

Figure 2.7: Increase the Amount of RAM

In the pop-up depicted in Figure 2.7, navigate to the “Memory” tab and increase the memory from 2048MB to 4096MB. That should be more than enough to run the virtual machine and all the various programs this semester.

STEP 10: Finishing the Setup

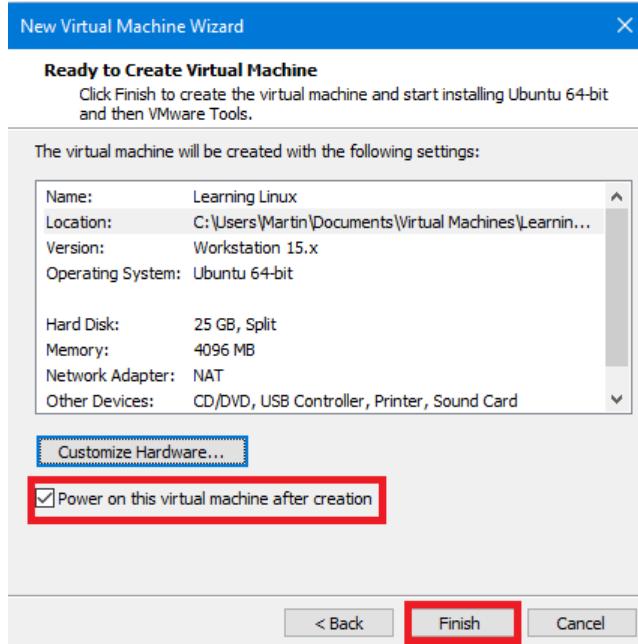

Figure 2.8: Finishing

Lastly, like in Figure 2.8, ensure the “Power on this virtual machine after create” is checked and then hit the “Finish” button. Once the virtual machine is created, it will power up and go through the automated setup process to configure the user account using the information provided in an earlier step.

STEP 11: Ubuntu Installation

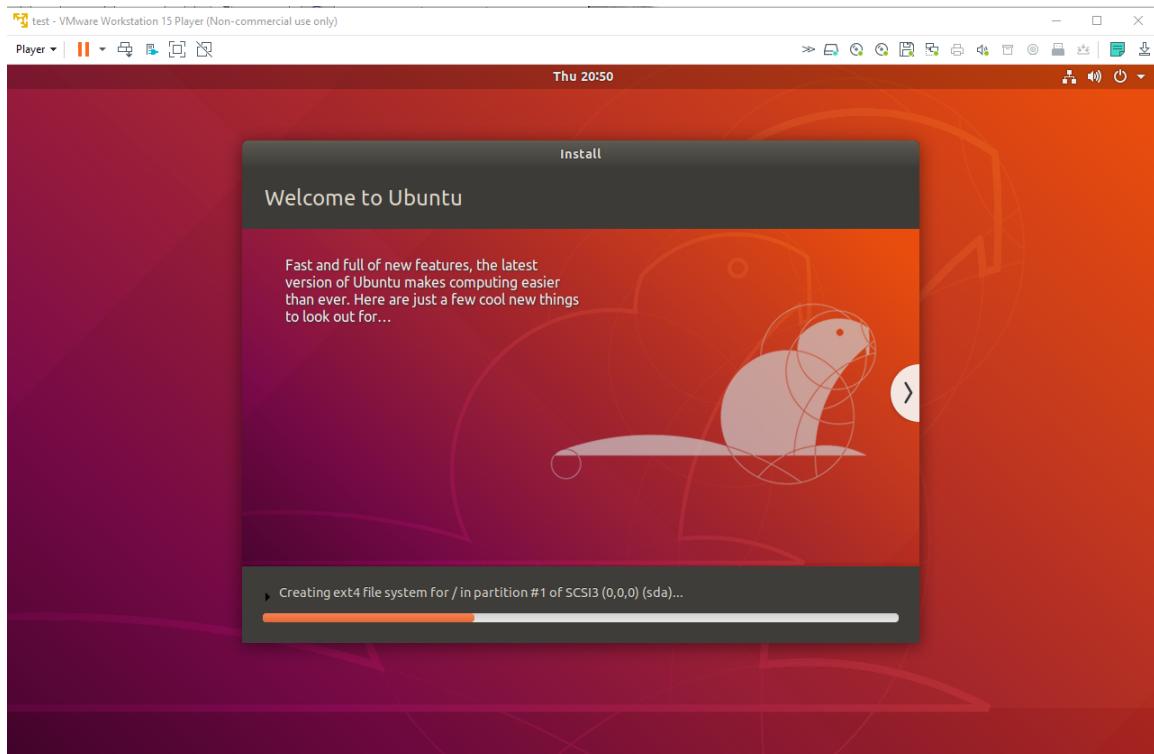

Figure 2.9: Ubuntu Installation

As in Figure 2.9 Ubuntu will be setup automatically since the easy install option was selected earlier. This process takes about 15-20 minutes.

STEP 12: Log Into the VM

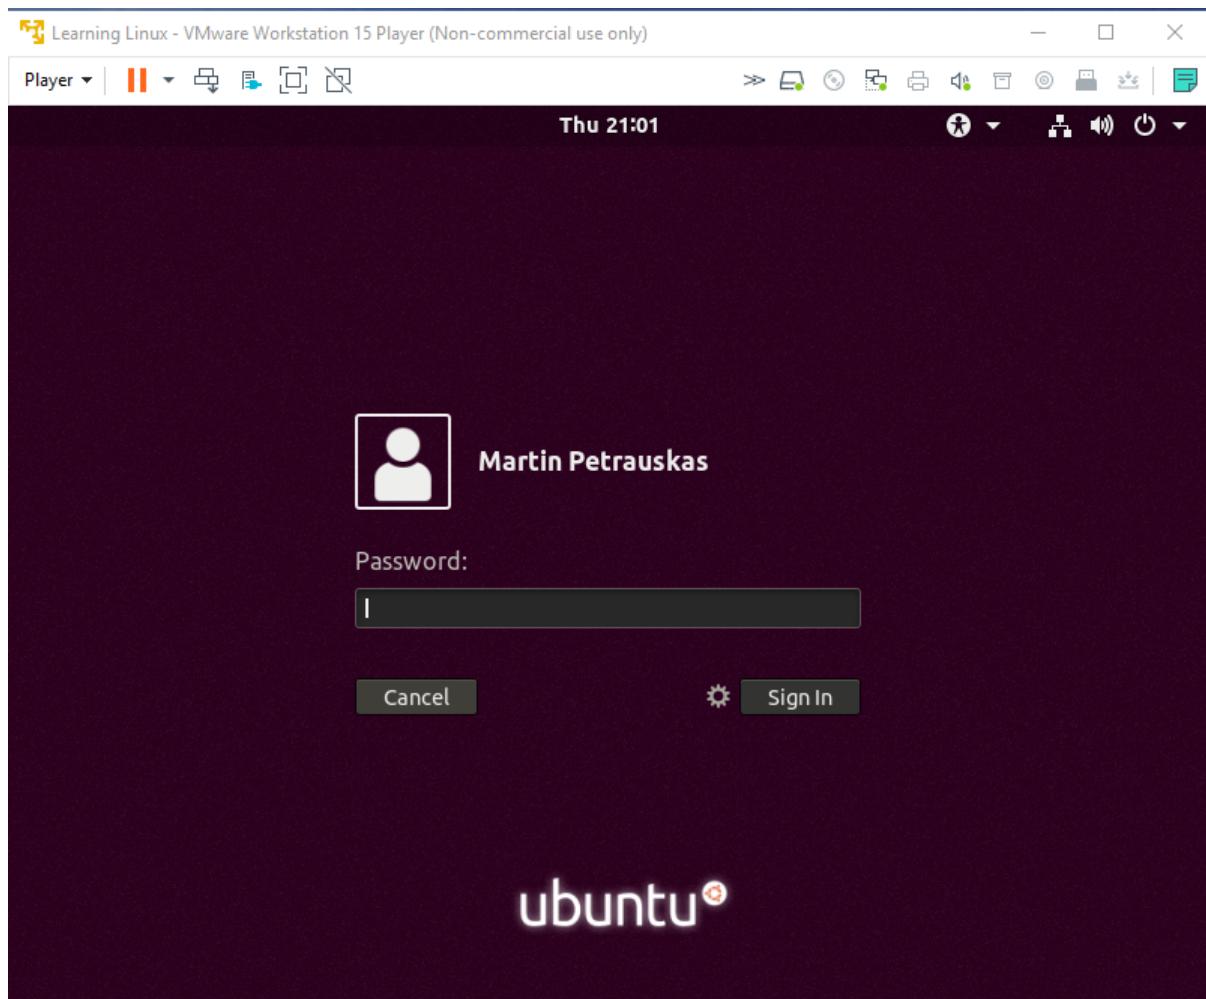

Figure 2.10: Logging In

Log into the VM like in 2.10 and you now have Ubuntu fully installed to start learning the command line.

Chapter 3

Creating a VM with VirtualBox

This chapter steps you through the process of creating a VM using the VirtualBox software.

STEP 3: Create a New Virtual Machine

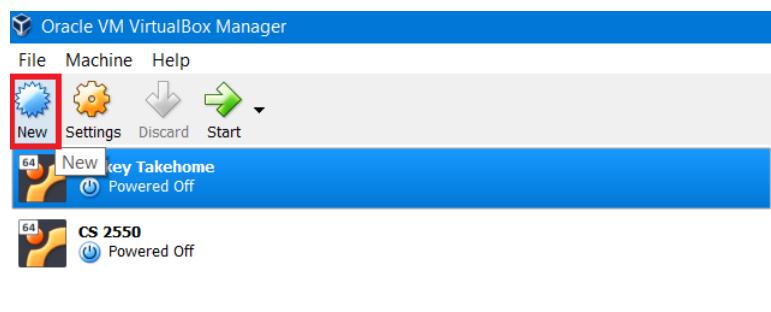

Figure 3.1: Creating a New VM

Start the VirtualBox program. In the upper left corner, click on the “New” button like in Figure 3.1.

STEP 4: Specify Virtual Machine Name and Type

Enter a simple name that describes the purpose of the virtual machine. Next, select “Linux” as the option for the type of machine. Then, select the proper Ubuntu version (32-bit or 64-bit). Click “Next” after entering the information.

STEP 5: Allocate RAM to the Virtual Machine

The Ubuntu OS recommends at least 2GB of RAM. Allocating anywhere between 4GB and 8GB is enough to use Ubuntu and learn how to use the command line. Then click “Next”.

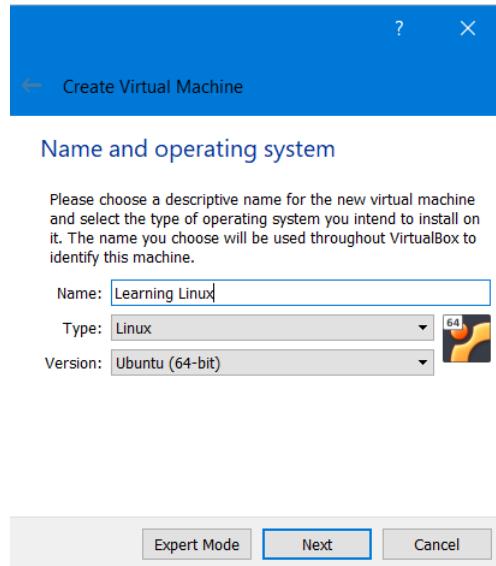

Figure 3.2: Name and Type of VM

STEP 6: Create the Virtual Hard Disk

Select the option “Create a virtual hard disk now”, and then click “Create”.

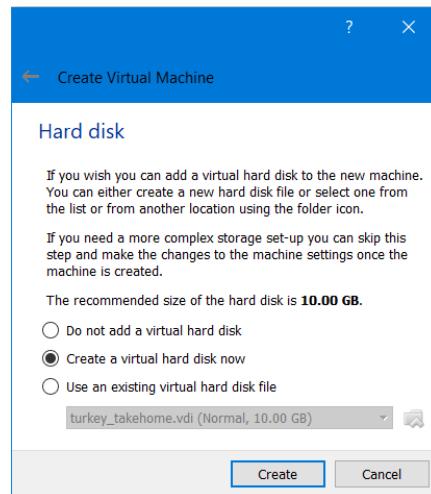

Figure 3.4: Creating a New Virtual Hard Disk

On the next screen, select the VirtualBox Disk Image (VDI) as the hard disk file type, and then click “Next”.

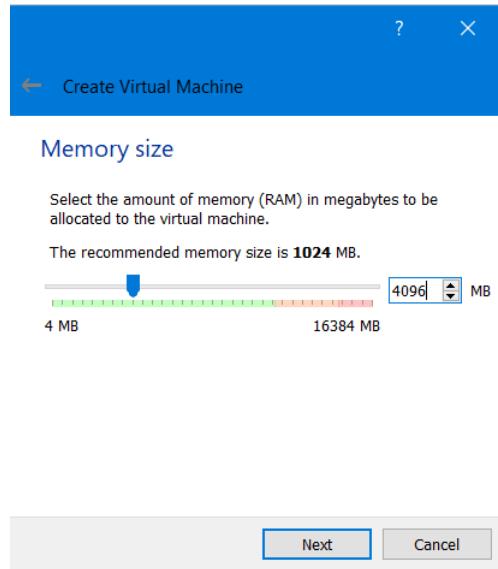

Figure 3.3: Allocating RAM

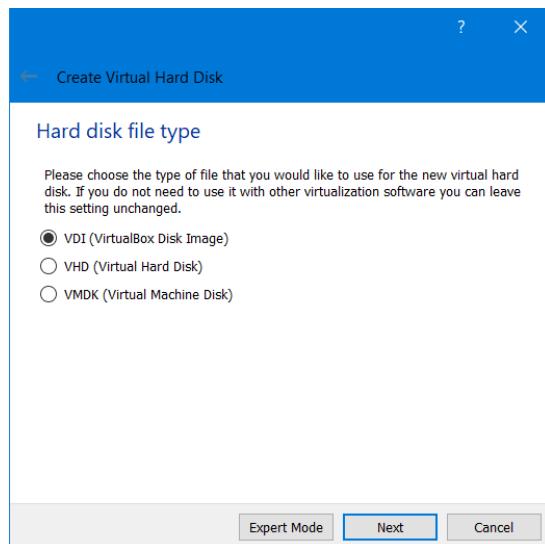

Figure 3.5: Select Hard Disk Type

Select the “Fixed size” option, and click “Next”.

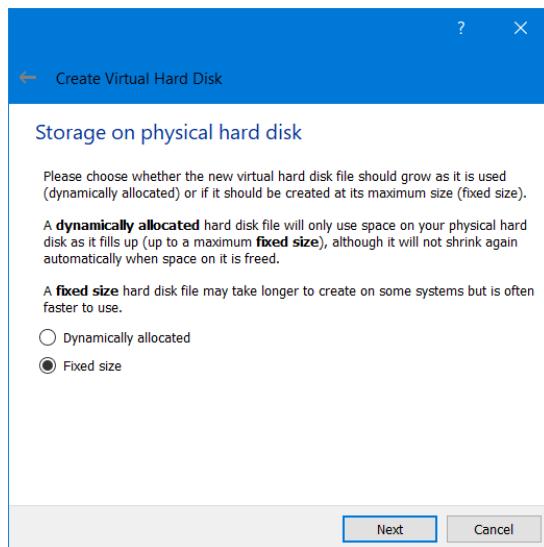

Figure 3.6: Hard Disk Storage Type

Allocate between 10GB and 25GB for the hard drive size, and then click “Create”.

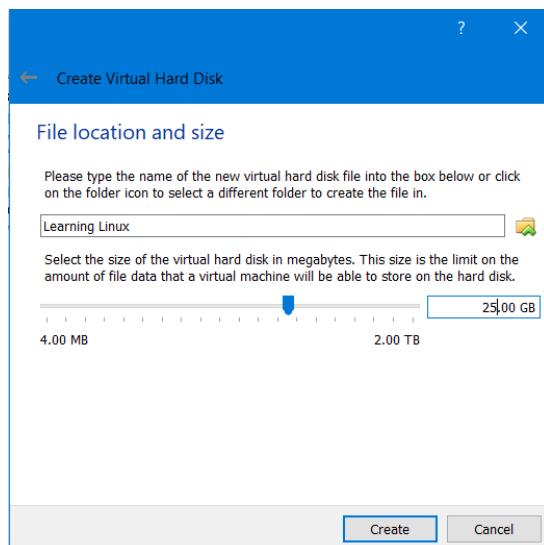

Figure 3.7: Hard Disk Size

Another screen shows the progress of the creation of the hard drive.

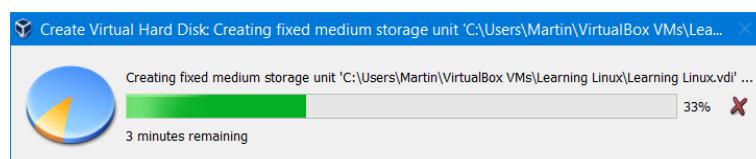

Figure 3.8: Progress

STEP 7: Configure Virtual Machine Settings

Before installing Ubuntu, some settings must be changed for the virtual machine to function properly.

To access the settings of the newly-created virtual machine, either click on the “Settings” button in the top left corner, or right click on the machine and click on “Settings”.

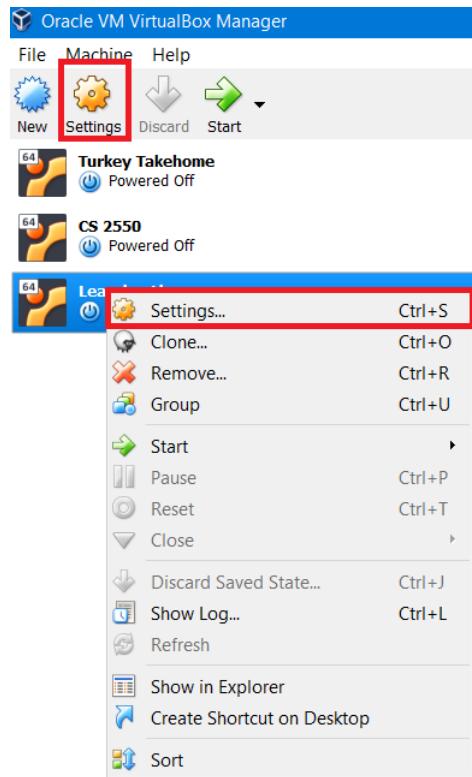

Figure 3.9: Virtual Machine Settings

The RAM, number of processors, and other options can be changed from the general settings panel.

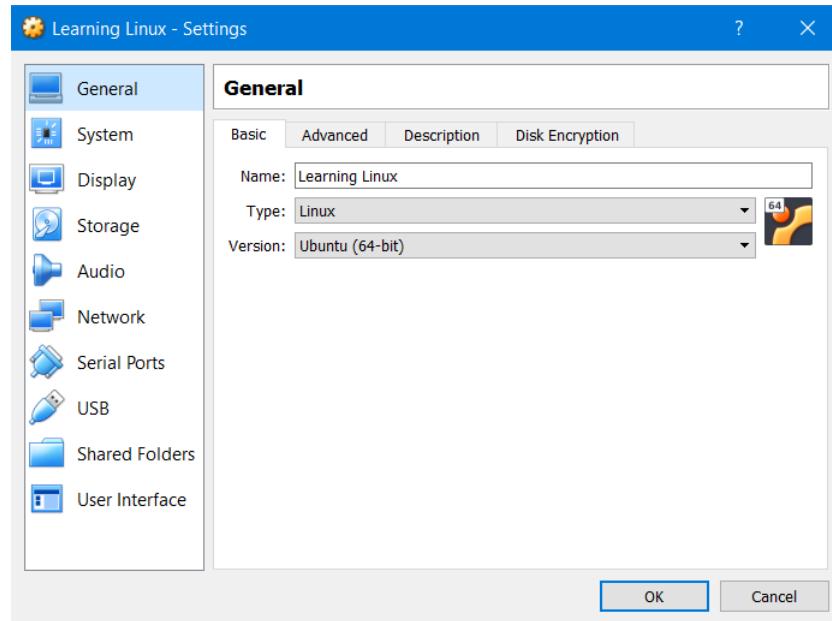

Figure 3.10: General Settings

Select “System” on the menu, and then go to the “Processor” tab. Select the option “Enable PAE/NX”.

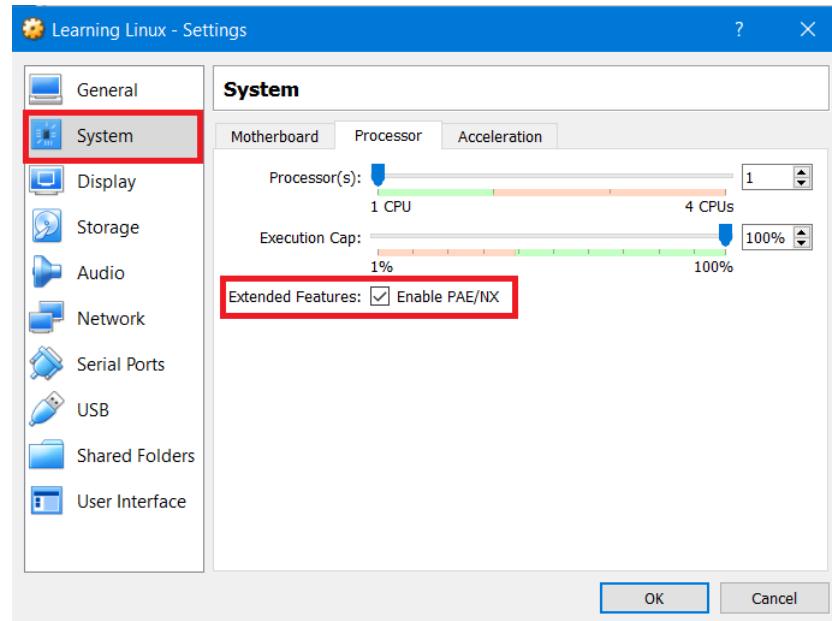

Figure 3.11: Enable PAE/NX

Note: this feature may need to be enabled or disabled for the virtual machine.

Select “Display” on the menu. Under the “Screen” tab, select “Enable 3D Acceleration”.

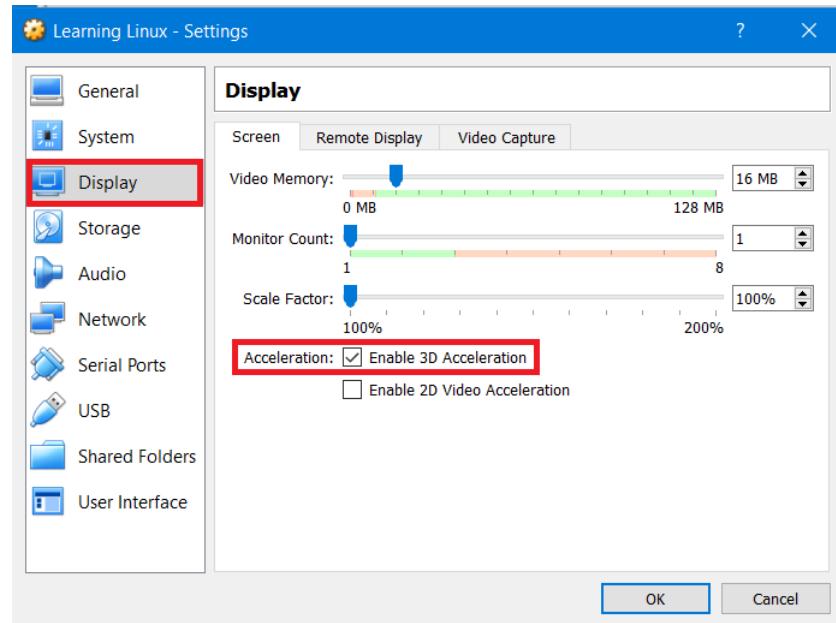

Figure 3.12: 3D Acceleration

Note: this feature may need to be enabled or disabled for the virtual machine.

Select “Storage” and click on “Empty” under “Controller: IDE”. Then click on the small image of a CD next to “Optical Drive”. A pop up screen will appear to select the Ubuntu ISO file. And then click “OK”.

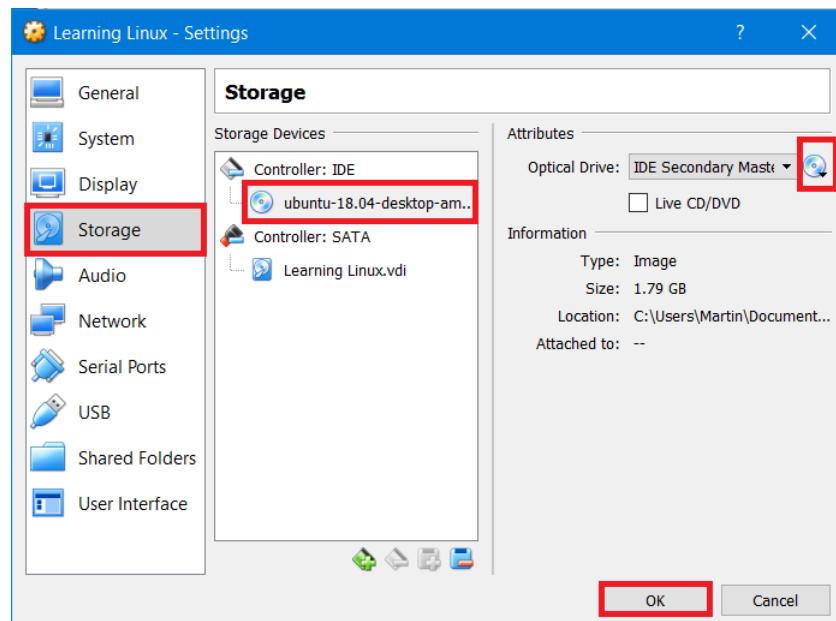

Figure 3.13: Mount the ISO Image

STEP 8: Install Ubuntu on the Virtual Machine

Select the virtual machine that was just created and click “Start”. Either click on the Start button in the upper left corner or right click on the virtual machine and then select the Start option.

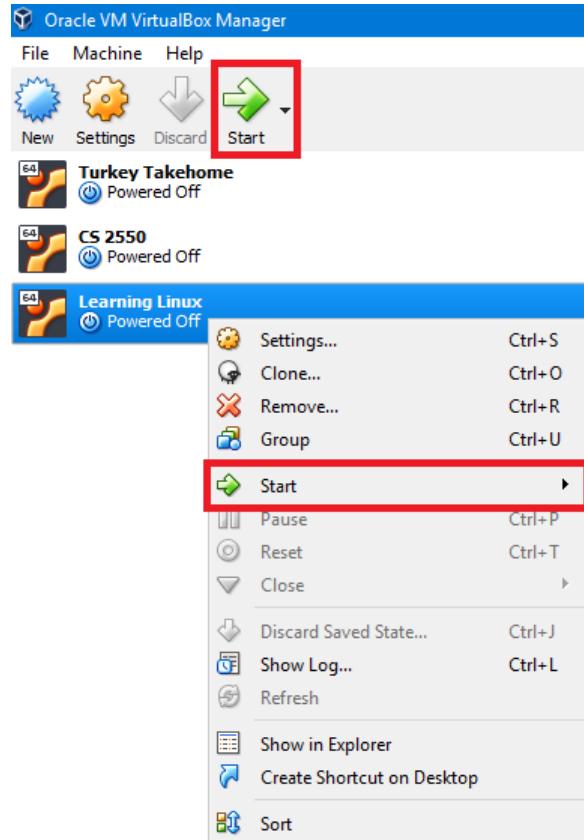

Figure 3.14: Start the VM

Once the machine is started, select “Install Ubuntu” on the screen that appears.

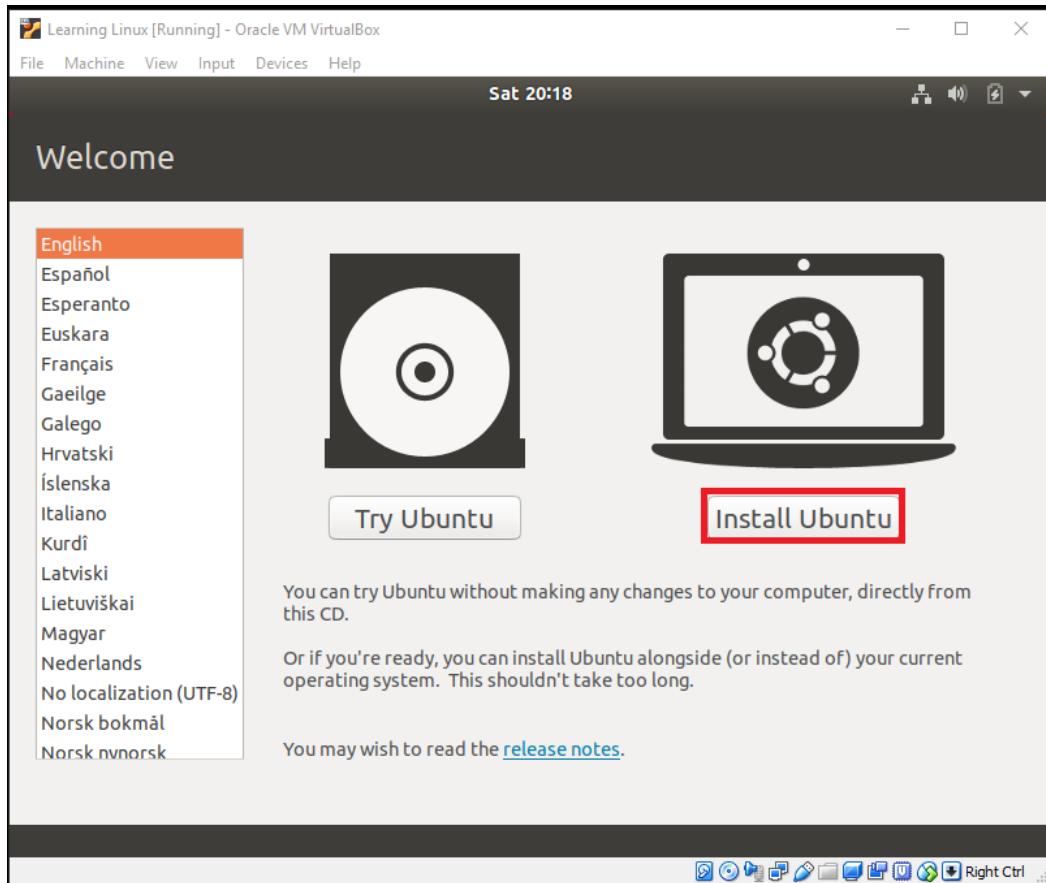

Figure 3.15: Install Ubuntu

On the next screen, select the keyboard layout that the Ubuntu OS will use. Then click “Continue”.

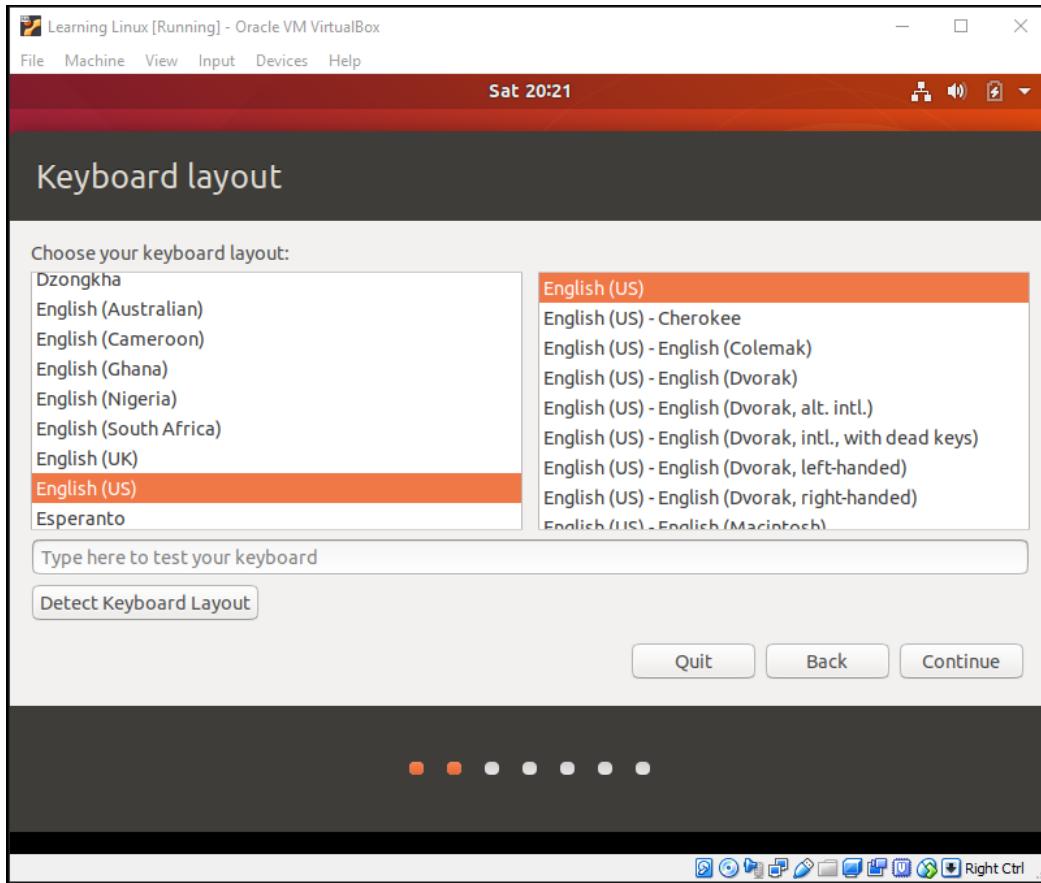

Figure 3.16: Choose a Keyboard Layout

Now select “Normal Installation” to install all the Ubuntu programs, And then select “Download updates while installing Ubuntu”. Then click “Continue”.

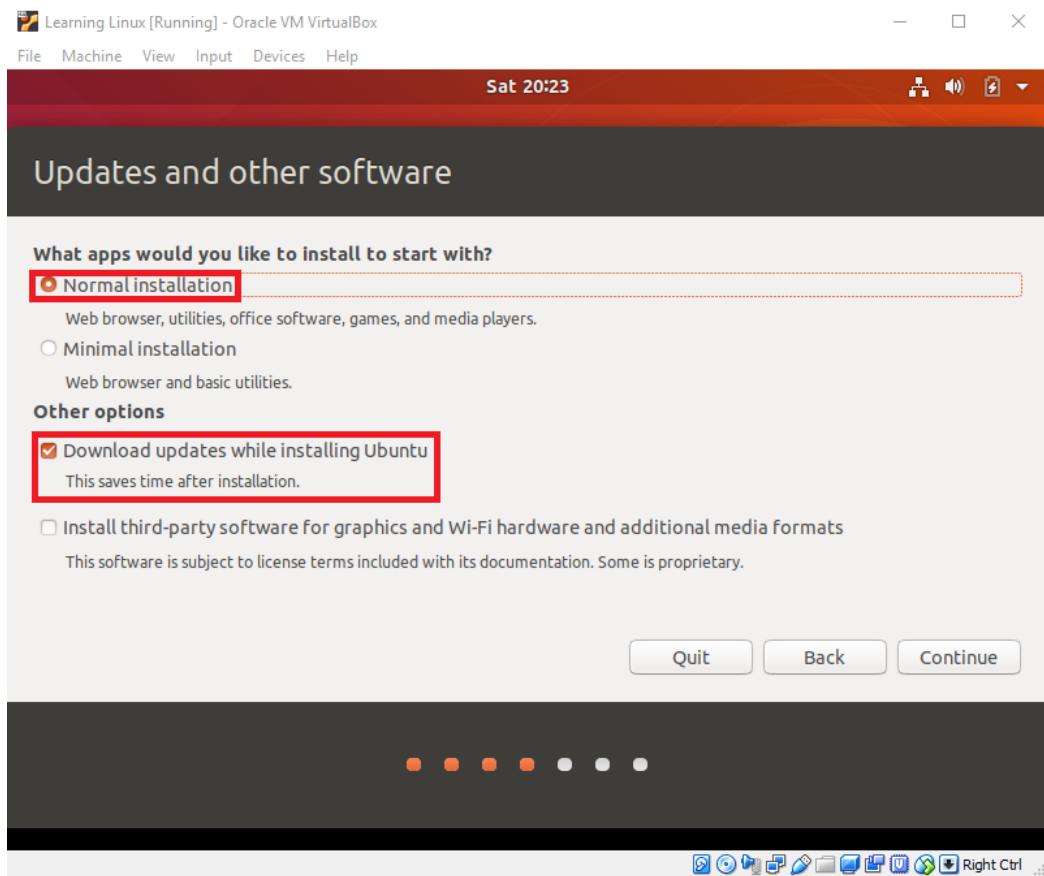

Figure 3.17: Normal Installation

Note: also select the “Install third-party software” if the wifi card or other hardware is incompatible with the virtual machine.

On the installation type screen, select “Erase disk and install Ubuntu” and click on “Install Now”.

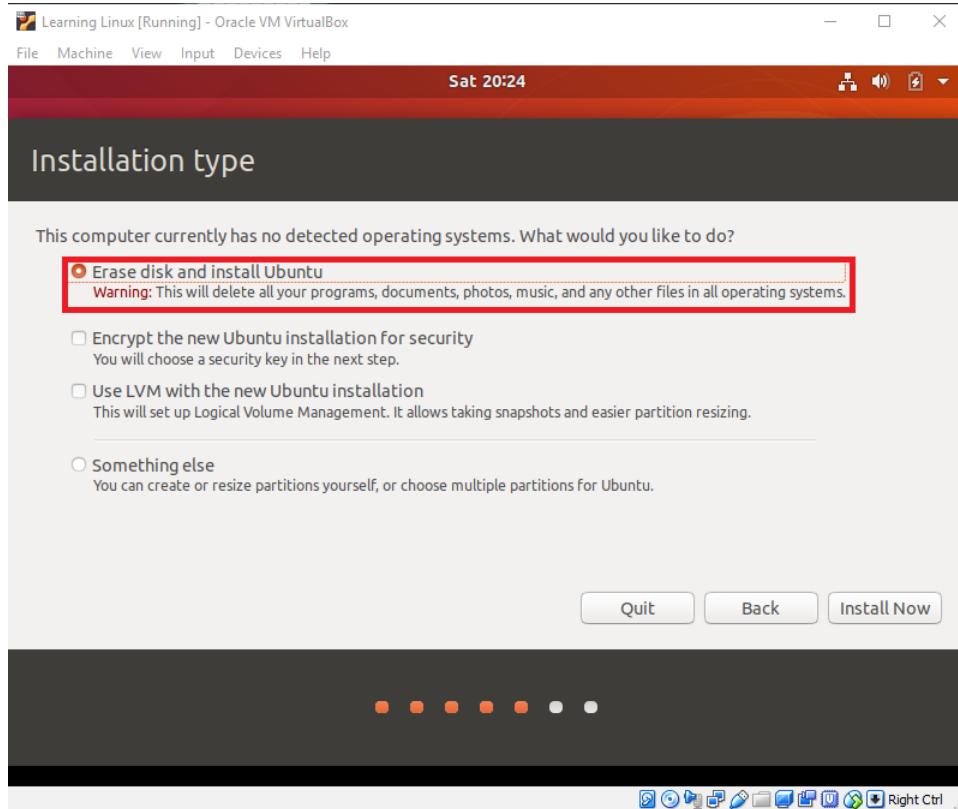

Figure 3.18: Erase Disk

A pop-up appears to confirm the changes. Then click on “Continue”.

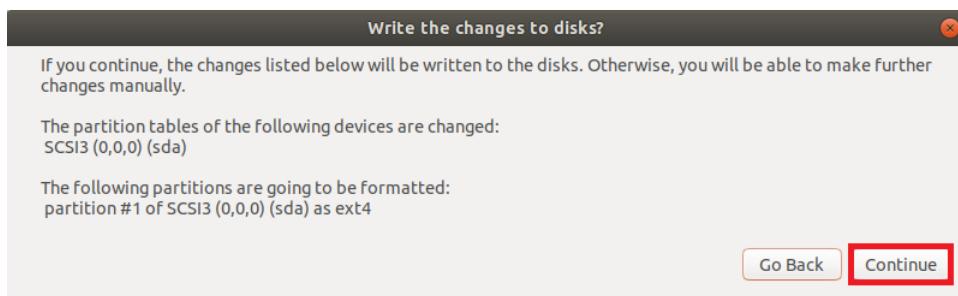

Figure 3.19: Continue with Changes

Type in the city to establish the proper timezone. Then click on “Continue”.

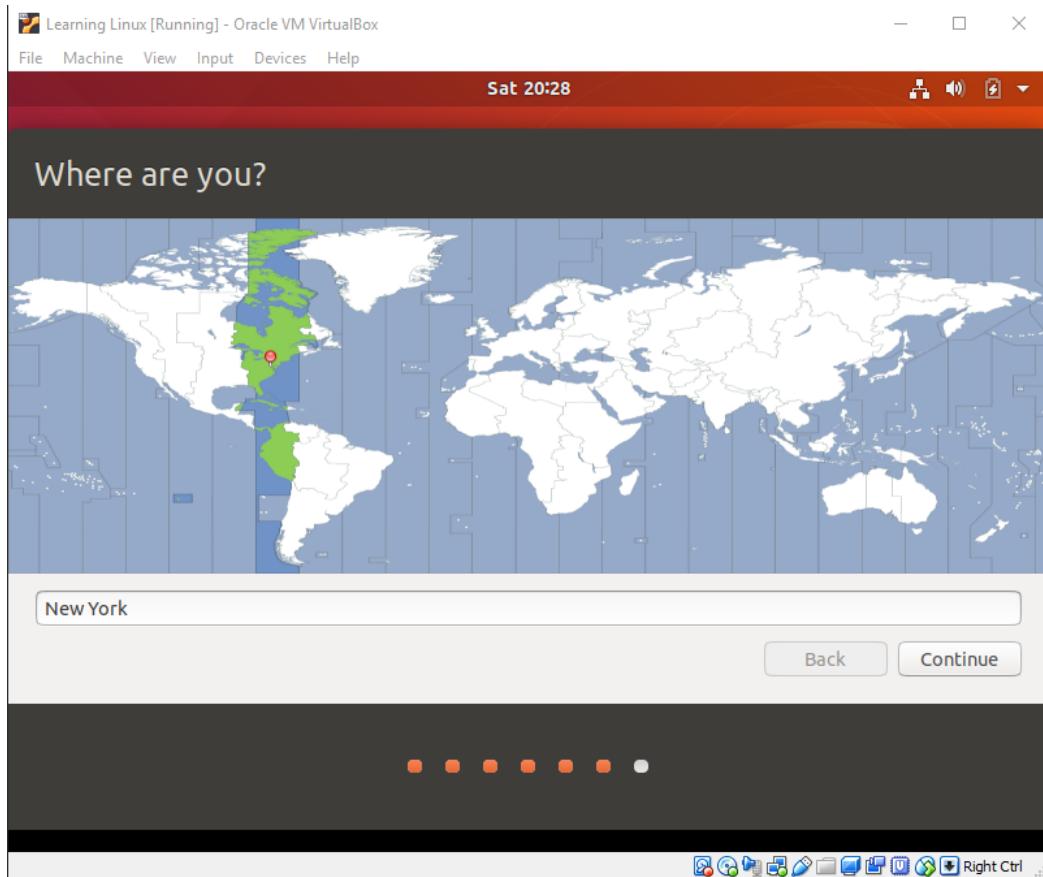

Figure 3.20: Select Proper Timezone

Enter the required information in every field. Then, click on “Continue”.

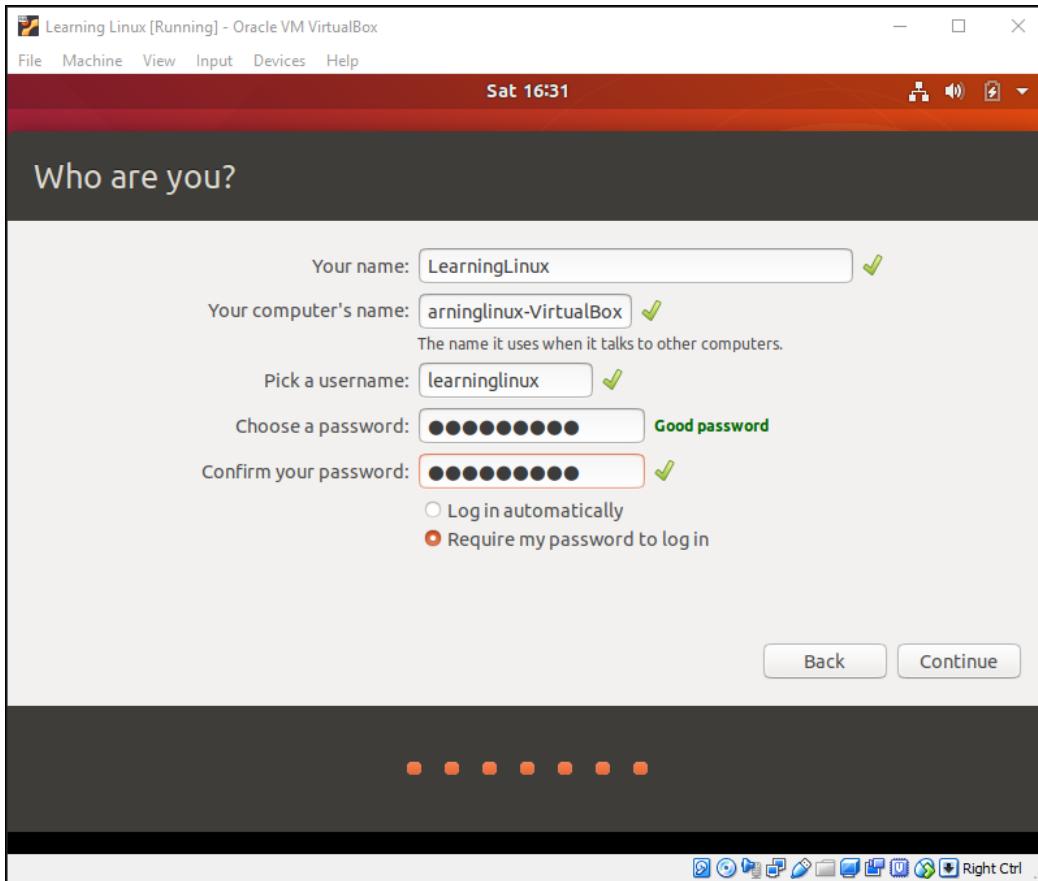

Figure 3.21: Enter User Credentials

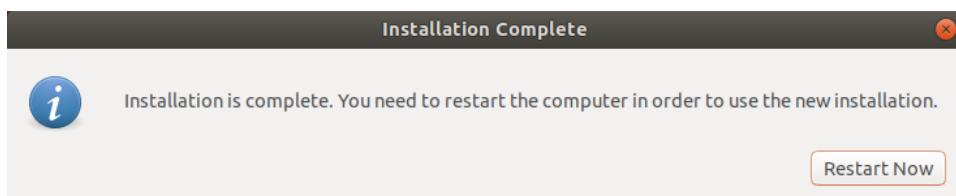

Figure 3.22: Installation is Now Complete

After the installation is completed, click on “Restart Now” to use the virtual machine.

Chapter 4

Basic Navigation of the Command Line

Definitions

1. **Root Directory** – the top-most directory in a file system structure
2. **Home Directory** – the file system directory for a given user on an operating system
3. **Current working directory** – the directory in which the user is currently in
4. **Absolute path** – the path of a file from the root directory
5. **Relative path** – the path of a file from the current working directory
6. **File system structure** – the organization of the files and directories of a computer

The Basic Navigation of the Command Line

There are many similarities between the file structure of a Windows/Mac OS and the Linux OS. However, some differences, such as the name of the home and root directories, should be noted.

On the Windows OS, the home directory is C:\Users\<USERNAME>. This is where user information is stored, such as documents, pictures, etc.. C:\ is the root directory of the entire computer. It is where the information for the computer is stored in different folders such as program files, operating system files, and other files.

Other devices connected to the computer have different corresponding root directories starting with another letter. Look at the following example of drive letter assignment on a computer.

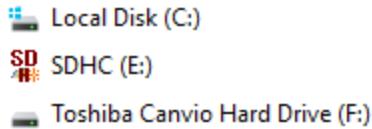

Figure 4.1: Windows Root Directories

C: is the root for the local disk, which is the computer, while E: is a SD card and F: is an external hard drive. Windows assigns the next free letter to the appropriate device. A file in the external hard drive might have the filepath of F:\projects\examples1.doc.

On a Linux-based operating system, the home directory is /home/<USERNAME>. Like the Windows OS, that is where all the user information is stored. However, one of the main differences is that the root directory for a Linux machine is /, which is a simple forward slash.

The location of other devices in a Linux computer will be explained in the end of this section.

Directory Structure

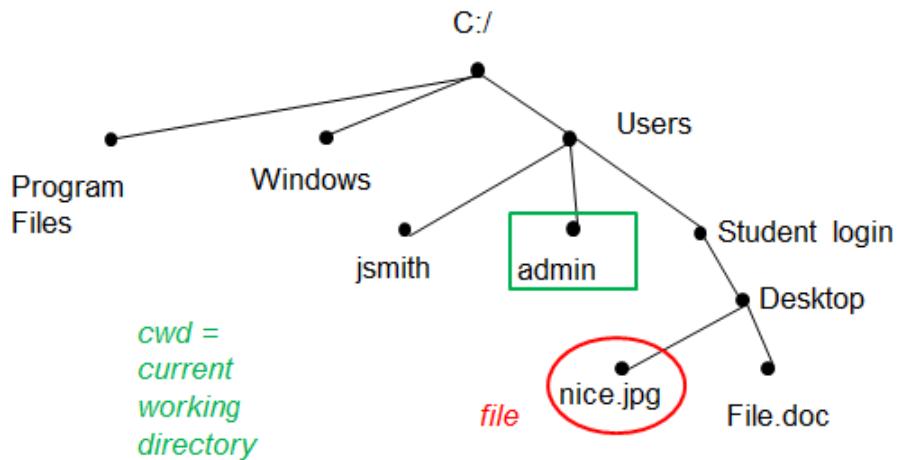

Figure 4.2: Windows Directory Structure

The above is an example of the directory structure on a Windows computer. The file system is hierarchical and it looks just like a tree. For a Linux machine it would have the same hierarchical structure with different directory names.

To navigate the directories of any operating system, it is necessary to have a basic understanding of the file system structure.

Absolute Paths vs. Relative Paths

An absolute filepath is the path for a file from the root directory, which in the diagram on p.22 is C:\ which is at the very top of the tree-like structure. For example, the absolute filepath for the file nice.jpg, which is circled in red in the above diagram, would be C:\Users\Student login\Desktop\nice.jpg.

A relative filepath is the path for a file from your current working directory, which, in the diagram on p.22, is the admin folder boxed in green. For example, the relative filepath to the file nice.jpg would be ..\Student login\Desktop\nice.jpg. Look closely at how the filepath starts. It starts with a two periods. This signifies going up one level in the directory structure from the admin directory to the Users directory.

Using the Terminal

Now that you know the basics of directories and filepaths, it is now time to start using the terminal.

To start up the terminal, right-click anywhere on the screen to display the below menu. One of the options is “Open Terminal”.

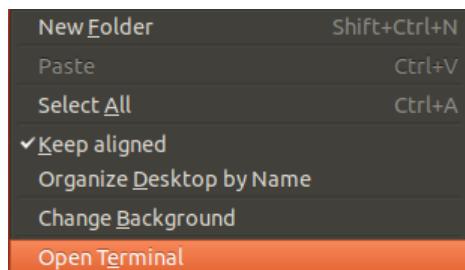

Figure 4.3: Starting the Terminal

Selecting “Open Terminal” displays the below terminal, and from there you can start to use the command line.

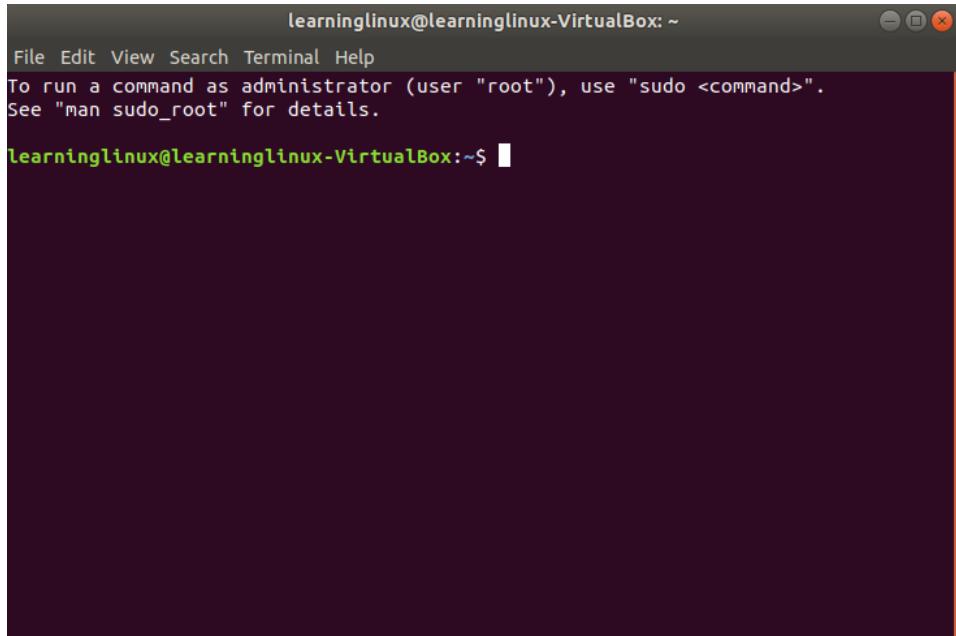

Figure 4.4: The Terminal

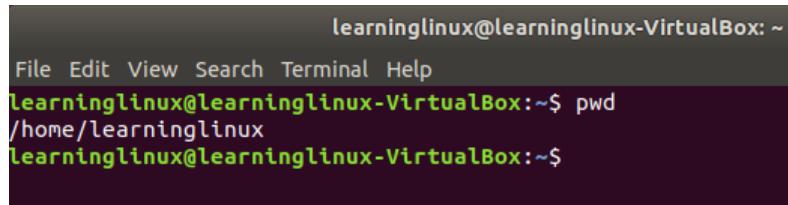

Entering Commands on the Terminal

Within the terminal, you have something called a shell. The shell is a command-line interface that interprets commands, defines how the terminal behaves, and how it looks after executing commands. On most Linux distributions, including Ubuntu, Bash is the default shell. Bash stands for Bourne-Again shell. Whenever you start a terminal, its location is always your home directory.

The terminal displays the following when it first starts up:

1. **learninglinux**: the username of the current user
2. **learninglinux-VirtualBox**: the name of your virtual computer
3. **~**: the current user's home directory, which in this case is `/home/learninglinux`
4. **\$**: prompt symbol, your input appears after this symbol

The **pwd** command stands for print working directory. The syntax for the command is as follows: `pwd [OPTIONS]`. Without any arguments, this command prints the absolute file path of the directory that you are currently in. Type `pwd` in your terminal to see the result. It should look similar to the following, but instead of learninglinux, it will display your username.

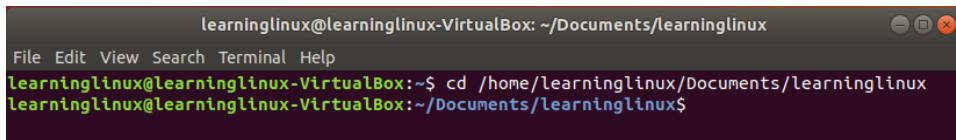

```
learninglinux@learninglinux-VirtualBox: ~
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ pwd
/home/learninglinux
learninglinux@learninglinux-VirtualBox:~$
```

Figure 4.5: **pwd** Command

Note: There are optional arguments for the **pwd** command, but you do not need to know them right now

To move to other directories, use the **cd** command, which stands for change directory. The syntax is **cd [DIR]**. DIR is an optional argument for the location of the directory you want to move to. If no argument is supplied, the **cd** command automatically goes back to the home directory.

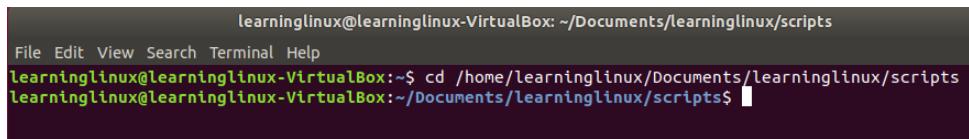

To use the **cd** command to move around, use either the absolute path or the relative path of the directory. There is a directory named learning Linux within my Documents directory. To change to this directory using the absolute path, type the command **cd /home/learninglinux/Documents/learninglinux**.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ cd /home/learninglinux/Documents/learninglinux
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 4.6: **cd** with Absolute Path

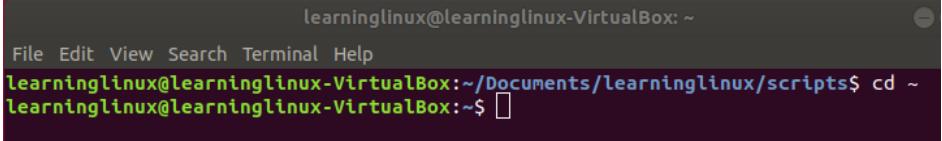

Another example is to go into the scripts directory, which is within the learninglinux directory. To do this, run the command **cd /home/learninglinux/Documents/learninglinux/scripts**.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ cd /home/learninglinux/Documents/learninglinux/scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 4.7: **cd** with Absolute Path

In both of these examples, the shell shows your current working directory, which starts off with **/Documents/learninglinux**. The **~** symbol shows up again and it has the same meaning as we mentioned before. It is a shortcut for the home directory. Now type in **cd ~**. This will change the directory back to the home directory.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~". The window has a dark background with light-colored text. At the top, there's a menu bar with "File", "Edit", "View", "Search", "Terminal", and "Help". Below the menu, the terminal prompt shows the user's name and host, followed by a tilde (~) indicating the home directory. The user then types the command "cd ~" and presses Enter. The cursor is shown at the end of the command line.

Figure 4.8: cd Home Directory

Viewing Directory Contents

To know what is in the directories use the **ls** command, which stands for list segments. The syntax for this command is **ls [OPTIONS] [FILE]**. By default, the command with no arguments will list all visible files and directories that are in the current directory. In later sections we will learn some of the other optional arguments. Enter **ls** in your terminal.

```
learninglinux@learninglinux-VirtualBox: ~
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ ls
Desktop    Downloads      Music      Public      Videos
Documents  examples.desktop Pictures  Templates
learninglinux@learninglinux-VirtualBox:~$
```

Figure 4.9: ls Command

As you can see above the different files and directories are color coded. The following table describes the color and their associated file type.

Color	File Type
White	Text Files
Blue	Directories
Green	Executables
Pink	Images
Red	Archives
Cyan	Links

Note: These colors may differ with different versions of the shell.

The **ls** command has numerous optional arguments that can be passed along with the command. Two of the most common arguments with the **ls** command are **a** and **l**. **a** will show all the contents of a directory, including hidden files and **l** will list more information about each item in the directory. Try both of these commands in the terminal.

```
learninglinux@learninglinux-VirtualBox:~$ ls -a
.
..
.cache examples.desktop myfile.txt Templates
.config .gnupg Pictures Videos
.bash_history Desktop .ICEauthority .profile .viminfo
.bash_logout Documents .local Public
.bashrc Downloads Music .sudo_as_admin_successful
learninglinux@learninglinux-VirtualBox:~$ ls -l
total 48
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Desktop
drwxr-xr-x 3 learninglinux learninglinux 4096 Aug  7 20:47 Documents
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Downloads
-rw-r--r-- 1 learninglinux learninglinux 8980 Jul 21 16:34 examples.desktop
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Music
-rw-r--r-- 1 learninglinux learninglinux   52 Aug 12 15:30 myfile.txt
drwxr-xr-x 2 learninglinux learninglinux 4096 Aug 22 21:43 Pictures
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Public
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Templates
drwxr-xr-x 2 learninglinux learninglinux 4096 Jul 21 16:42 Videos
learninglinux@learninglinux-VirtualBox:~$
```

Figure 4.10: Listing Hidden Files

Look closely at the left most column of the output of `ls -a`. The first two items displayed are a “.” and “..”. These are very important in the file system structure. Both of these will always be present in a directory, no matter which one it is. The single period represents the current directory you are in, and the double period represents the parent directory.

To move around from one directory to another using relative paths, enter the name of the directory relative to the current working directory. For example, to go from the home directory to the `Documents` directory, type the command `cd Documents`.

```
learninglinux@learninglinux-VirtualBox: ~/Documents
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ cd Documents
learninglinux@learninglinux-VirtualBox:~/Documents$
```

Figure 4.11: cd Relative Path

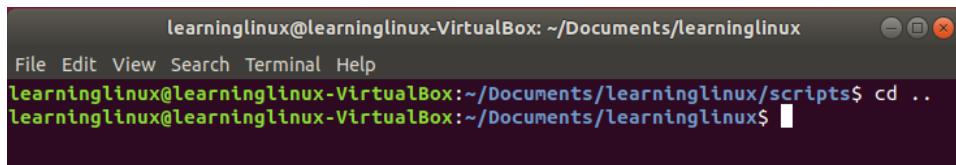

You can also move several directories down at a time. Within the `Documents` directory, there is a directory named `learninglinux`, and within that directory, there is one called `scripts`. To get to that directory in one command, type in the command `cd Documents/learninglinux/scripts`.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~$ cd Documents/learninglinux/scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 4.12: cd Relative Path 2

Note: You may run into some issues with directory names if they contain spaces or other special characters. These types of issues will be discussed in a Chapter 7 Complex Inputs

So far, all the commands have been going down into directories. But there are ways to go back up in the file system structure. Right now, the current working directory is `Documents/learninglinux/scripts`. To get to the `Documents/learninglinux` directory, type in the command `cd ..`. The two periods after `cd` signifies the parent directory, which is up one level in the directory structure.

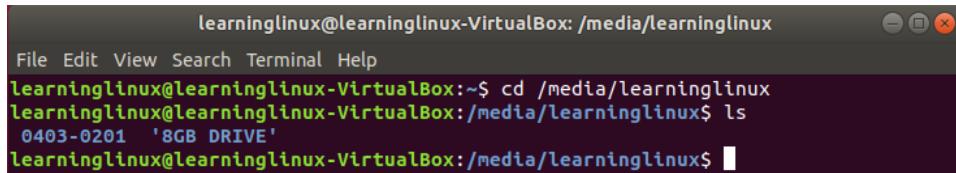

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux". The window has a standard Linux-style title bar with icons for minimize, maximize, and close. The terminal menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". The command line shows the user's session: "learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux\$ cd ..", followed by the prompt "learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux\$".

Figure 4.13: `cd` Parent Directory

Linux Devices

Other devices on Linux are stored in the `media` directory. Use the command `cd /media/<USERNAME>` to navigate to the directory that may contain other devices. This is yet another example of using the absolute path with the `cd` command.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: /media/learninglinux". The window has a standard Linux-style title bar with icons for minimize, maximize, and close. The terminal menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". The command line shows the user's session: "learninglinux@learninglinux-VirtualBox:~\$ cd /media/learninglinux", "learninglinux@learninglinux-VirtualBox:/media/learninglinux\$ ls", and "learninglinux@learninglinux-VirtualBox:/media/learninglinux\$".

Figure 4.14: Media Directory

This directory contains the other devices that are connected to the Linux machine at the moment. There are two: the first one is an SD card, and the second is a flash drive. To see the contents of these drives, change into the appropriate directory using the `cd` command.

Command Summary

Command	Purpose
pwd	print name of current/working directory
cd or cd ~	change the working directory to the home directory
cd [DIR]	change the working directory to DIR
cd ..	change the working directory to the parent directory
ls	list directory contents
ls -a	list directory contents including hidden files
ls -l	list directory contents with details

Chapter 5

File Basics

Definitions

1. **File** – a computer resource for recording data that is accessible by the operating system, programs, and the user
2. **Character Encoding** – a mapping of characters to bytes so that a computer can interpret characters properly
3. **Bit** – the smallest unit of data that can be represented on a computer
4. **Byte** – unit of data comprised of eight bits

This section covers what a file is, what character encoding is, and how to create files from the command line.

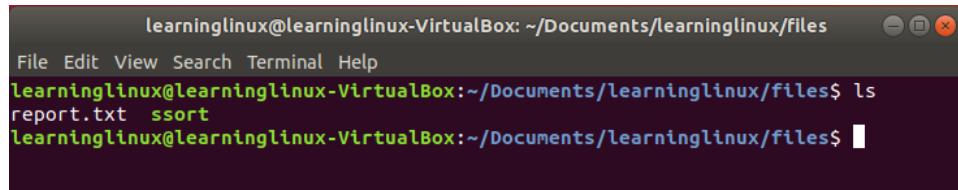

Files

A file is simply a sequence of bytes written on a computer storage device, such as a hard drive, flash drive or other device, that is accessible by the operating system, different programs, and the user. In essence, files are an abstraction for organizing groups of bytes that go together. For example, a Word document might contain text, a table, a couple charts, and some meta-data about how to format all of the before-mentioned content. All of these bytes are stored together in a single file since we consider them all to be part of the same document.

Text and Binary Files

There is a distinction to be made between text files and binary files. Text files contain human readable text while binary files contain data that cannot be interpreted by a human, and only by a computer program.

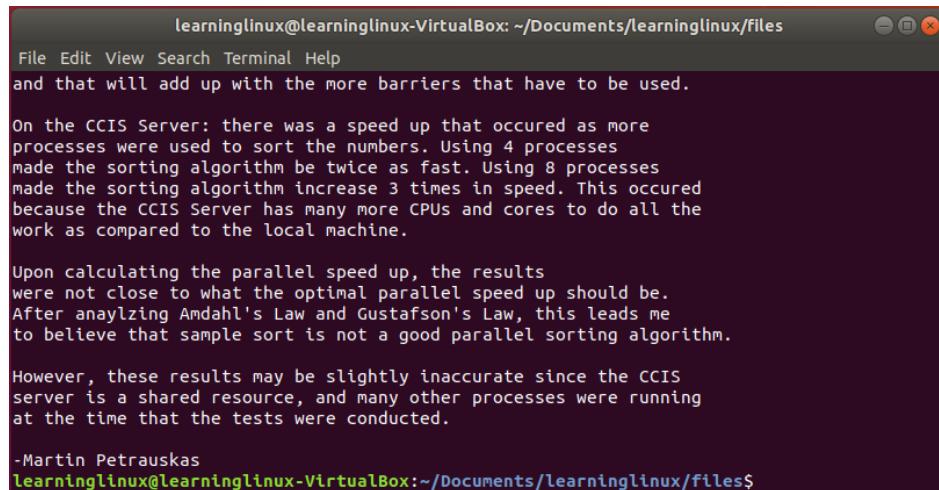

The result of running the **ls** command in the **files** directory is two files. One regular text file, and binary file.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/files
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$ ls
report.txt ssort
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$
```

Figure 5.1: ls Command

To see the information in the file, use the **cat** command, which stands for concatenation. The syntax for this command is **cat [OPTION] [FILE]**. The result of running the *cat report.txt* on the regular text file is the following.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/files
File Edit View Search Terminal Help
and that will add up with the more barriers that have to be used.

On the CCIS Server: there was a speed up that occurred as more
processes were used to sort the numbers. Using 4 processes
made the sorting algorithm be twice as fast. Using 8 processes
made the sorting algorithm increase 3 times in speed. This occurred
because the CCIS Server has many more CPUs and cores to do all the
work as compared to the local machine.

Upon calculating the parallel speed up, the results
were not close to what the optimal parallel speed up should be.
After analyzing Amdahl's Law and Gustafson's Law, this leads me
to believe that sample sort is not a good parallel sorting algorithm.

However, these results may be slightly inaccurate since the CCIS
server is a shared resource, and many other processes were running
at the time that the tests were conducted.

-Martin Petrauskas
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$
```

Figure 5.2: cat Command

As you can see, it is definitely human readable text.

Now, if we run *cat ssort*, we will not see any human readable text.

Figure 5.3: cat Command 2

Other than the occasional character that can be interpreted, the output of the binary is unreadable.

Character Encoding

Computers can only interpret bits, which store binary values of 0 or 1. This means that they cannot interpret characters like 'a', '4', or '%'. These characters are stored in the computer as one or more bytes. As a result, a character encoding maps computer bytes and the characters a person sees on the screen.

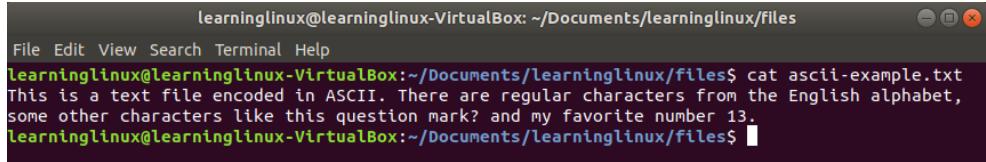

ASCII - American Standard Code for Information Interchange

ASCII is the oldest standard for character encoding. All ASCII characters are encoded using one byte of information (8 bits). However, this limits the number of characters that can be encoded to 2^8 , which is 256 characters, such as the English alphabet, roman numerals, and some special characters.

The following is a table of characters encoded with ASCII:

Decimal	Binary	Character
0	00000000	NULL
42	00101010	*
77	001001101	M
13	00001101	CR (carriage return)
7	00000111	BELL

And the following is an example of a file encoded in ASCII.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/files
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$ cat ascii-example.txt
This is a text file encoded in ASCII. There are regular characters from the English alphabet,
some other characters like this question mark? and my favorite number 13.
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$
```

Figure 5.4: ASCII Encoded File

UTF - Unicode Transformation Format

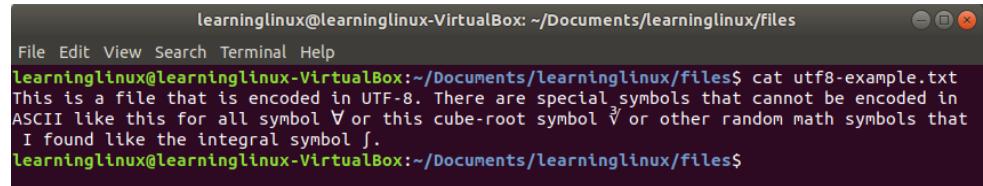

ASCII was a good start for encoding characters, but what about all the other characters that are found in different languages? Those could not be represented with the number of characters that ASCII is limited to.

In 1987, people from Xerox and Apple set out to make a universal character set that would include characters from all the different languages of the world. The major character encodings in UTF are UTF-8, UTF-16, and UTF-32.

UTF-8 is the most common encoding and uses four bytes to encode a character. It was designed to be backwards compatible with ASCII. This means that the first byte of information in UTF-8 has the same character mappings as ASCII.

Because of this backwards compatibility, whenever you are coding or typing a file, it will default to an ASCII text file, but as soon as it encounters a non-ASCII character, the file will then be encoded in UTF-8.

Here is an example of a file encoded in UTF-8.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/files
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$ cat utf8-example.txt
This is a file that is encoded in UTF-8. There are special symbols that cannot be encoded in
ASCII like this for all symbol √ or this cube-root symbol ∛ or other random math symbols that
I found like the integral symbol ∫.
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/files$
```

Figure 5.5: UTF-8 Encoded File

Line Endings

Any machine that runs DOS/Windows uses different line endings than a machine that runs Unix. On Windows machines line endings are “\r\n”, which is the carriage return followed by a newline. However, in Unix the line endings in just the newline represented by “\n”.

There is a command that can be used to convert the file endings from Dos style to Unix style and this program is called **dos2unix**. The syntax for this command is `dos2unix FILE`, which would convert all the line endings in the FILE to the proper Unix-style line endings.

File Extensions

File extensions are the endings attached to the names of files, such as exe (executable), jpg (picture), doc (document) and many others. These extensions signal to the operating system how the files should be interpreted and how the bytes of information are arranged.

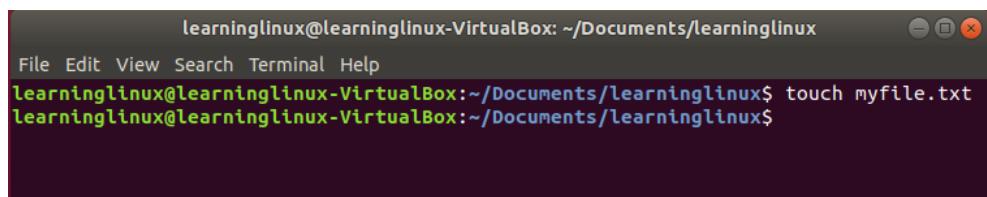

Operating systems rely on file extensions to find the proper program to open a file. It would be bad if Notepad++ tried to open a mp3 file. This is very common in graphical interfaces when a user can double click on a file, and the corresponding program will open the file.

However, command lines do not care about file extensions, and for the most part, they will not associate a file with any type of program. There is a small exception on Windows OS where the command line will assume a file is executable if it has the extensions exe. This issue does not arise in Linux because file permissions denote if a file is executable. File permissions will be explained in Chapter 5.

Creating a New File

To create a file from the command line, there are several commands that can be used.

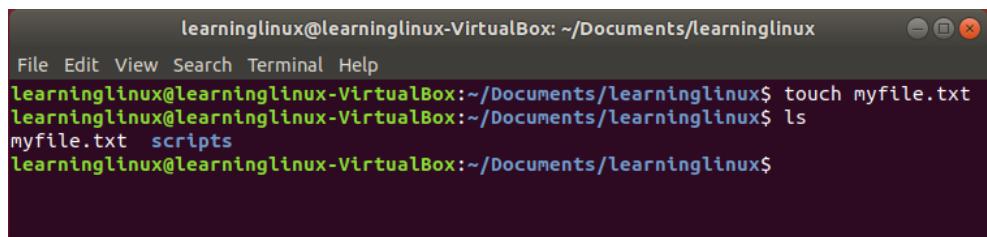

If you want to create an empty file, use the **touch** command. The syntax for the command is **touch [OPTION] [FILE]**. Go to the terminal and type *touch myfile.txt*.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ touch myfile.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 5.6: touch Command

This creates a text file called `myfile.txt` in your current directory. To check that the file is there, enter the `ls` command.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ touch myfile.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
myfile.txt  scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 5.7: touch Command 2

Another way to create a new file is to use a command line text editor such as **vim** or **emacs**. The syntax for these commands are `vim [FILE]` or `emacs [FILE]` and these a text editor will open up on the command line so that content can be added.

Command Summary

Command	Purpose
<code>touch [FILENAME]</code>	creates an empty file named FILENAME
<code>cat [FILENAME]</code>	displays the contents of FILENAME
<code>vim [FILE]</code>	opens the FILE with the vim text editor
<code>emacs [FILE]</code>	opens the FILE with the emacs text editors
<code>dos2unix [FILE]</code>	converts the FILE to Unix-style line endings

Chapter 6

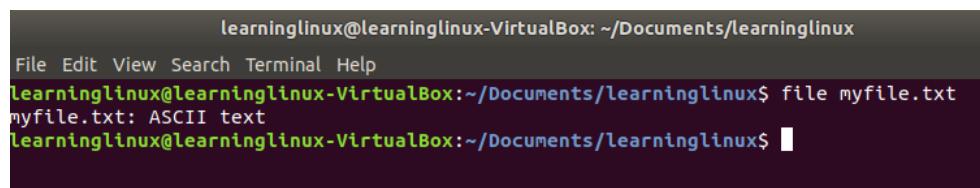

File Manipulation

In this section, you will learn about files names, creating, moving, copying, and deleting directories and files.

File Names In Linux

File names in Linux are case sensitive. That means the name of the file is specific to the uppercase and lowercase characters. For example, if a file is named `myfile.txt`, and we try to open a file named `MYFILE.txt`, an error message will appear. These are two distinct files.

To determine a file type, use the command `file`. The syntax for this command is `file [FILENAME]`. At the terminal, type in `file myfile.txt`.

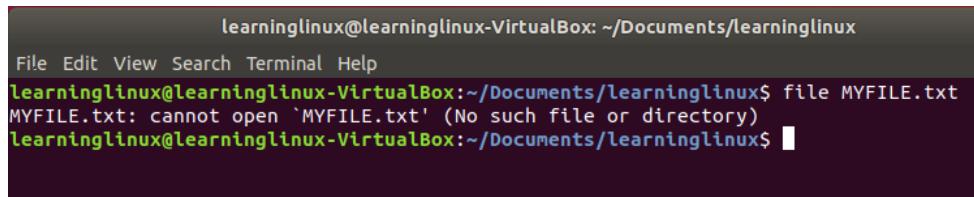

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux". The window shows a menu bar with "File Edit View Search Terminal Help". Below the menu, the command "file myfile.txt" is entered and its output is displayed: "myfile.txt: ASCII text".

```
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ file myfile.txt
myfile.txt: ASCII text
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.1: file Command

The output is the name of the file, which is `myfile.txt`, followed by the type of file, which is a basic text file encoded in ASCII.

Try the command `file MYFILE.txt` and an error message appears that the file does not exist.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ file MYFILE.txt
MYFILE.txt: cannot open 'MYFILE.txt' (No such file or directory)
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.2: file Command Error

In the Windows and Mac OS, myfile.txt and MYFILE.txt would refer to the same file. If you have a file named myfile.txt and you try to create a file named MYFILE.txt, you will see the following error message in Windows.

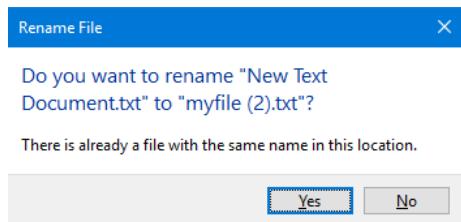

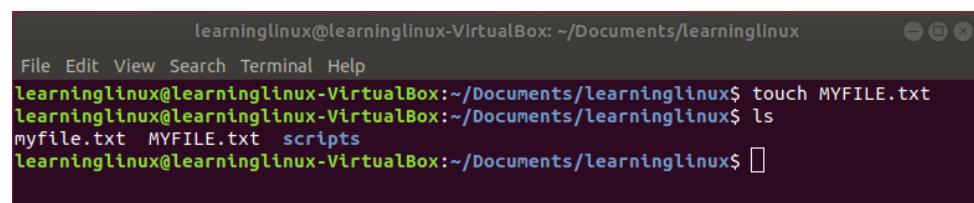

Figure 6.3: Windows File Error

These operating systems regard the files as the same even though their case is different. In the following figure, you can see that I created a file named MYFILE.txt and Linux does not display an error message. Looking at the directory contents, you can see two distinct files.

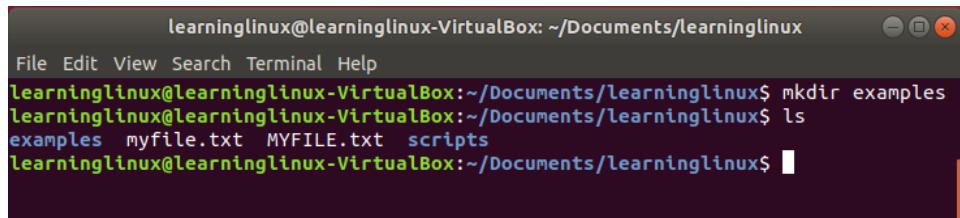

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ touch MYFILE.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
myfile.txt MYFILE.txt scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.4: touch Command

Creating Directories

To make directories from the command line, use the command **mkdir**, which is shorthand for make directory. The syntax for the command is **mkdir [OPTIONS] DIRECTORY**. At the terminal, type in *mkdir examples*. This will create a directory named examples.

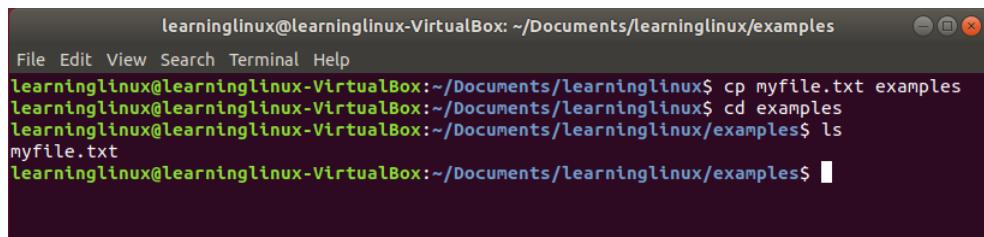

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ mkdir examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples myfile.txt MYFILE.txt scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.5: mkdir Command

Copying Files and Directories

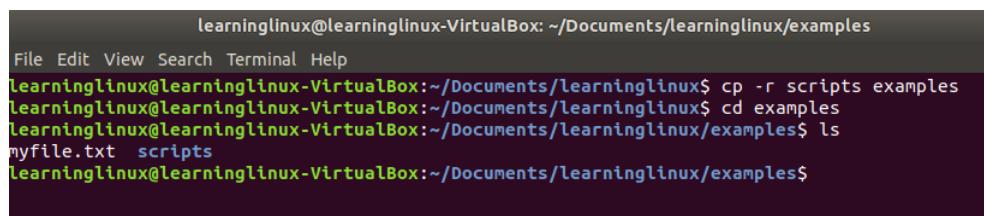

To copy files and directories, use the **cp** command, which is shorthand for copy. The syntax for the command is **cp [OPTIONS] SOURCE DEST**, where SOURCE is the file or directory you want to copy and DEST is the destination. The command to copy *myfile.txt* from the current directory to the newly created *examples* directory is *cp myfile.txt examples*.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cp myfile.txt examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cd examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls
myfile.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$
```

Figure 6.6: cp File

Additionally, an entire directory can be copied instead of one file. The command to copy the *scripts* directory into the *examples* directory is *cp -r scripts examples*. In this case, the optional argument **r** is required to recursively copies all the contents of the *scripts* directory into the *examples* directory.

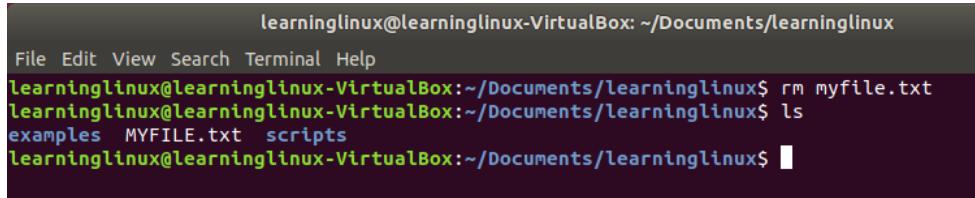

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cp -r scripts examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cd examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls
myfile.txt scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$
```

Figure 6.7: cp Directory

Deleting Files and Directories

To remove files or directories, use the **rm** command, which is shorthand for remove. The syntax for the command is **rm [OPTIONS] [FILE]**.

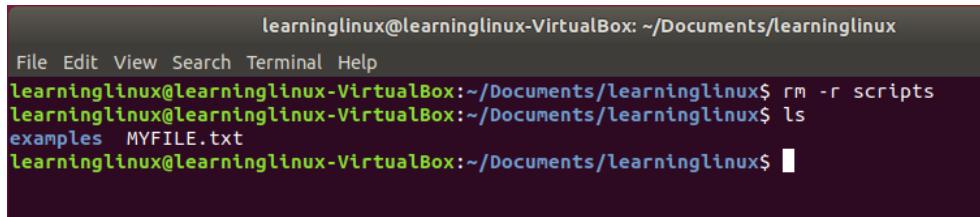

Navigate to the directory where you want to remove a file. Run the command `rm myfile.txt`. This will delete the file named `myfile.txt`.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ rm myfile.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples MYFILE.txt scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.8: rm File

You can also use the `rm` command to delete an entire directory. To delete the directory `scripts`, go to the directory which contains `scripts` and run the command `rm -r scripts`. The `r` is an additional argument that removes directory contents recursively.

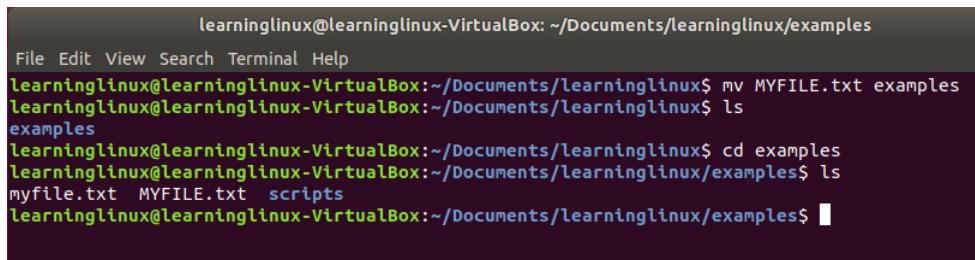

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ rm -r scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples MYFILE.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.9: rm Directory

Note: Remember to include the `r` argument when making changes to entire directories. An error message will be shown if this argument is not included.

Moving Files and Directories

To move files and directories, use the command `mv`, which is shorthand for move. The syntax for this command is `mv [OPTION] SOURCE DIRECTORY`, where `SOURCE` is the file or directory to be moved, and `DIRECTORY` is the destination of the source. To move `MYFILE.txt` from the current directory to the `examples` directory, use the command `mv MYFILE.txt examples`.

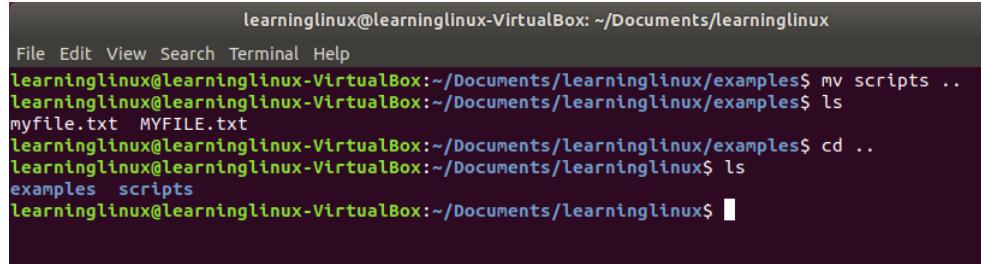

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ mv MYFILE.txt examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cd examples
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls
myfile.txt MYFILE.txt scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$
```

Figure 6.10: mv File

The **mv** command can also be used to move entire directories. To move the scripts directory out of the examples directory up one level, use the command *mv scripts ..*

Note: The two periods mean you are going up one level in the directory structure

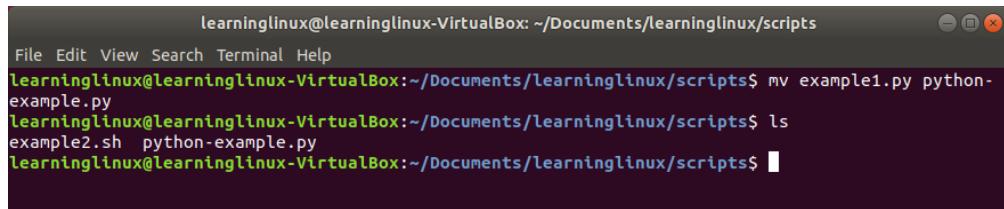

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ mv scripts ..
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls
myfile.txt MYFILE.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ cd ..
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 6.11: mv Directory

Renaming Files

The **mv** command can also be used to rename files. In the *scripts* directory, there is a file named *example1.py*. To rename the file, type in the command *mv example1.py python-example.py*. This will rename the file *example1.py* to *python-example.py*.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ mv example1.py python-
example.py
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ ls
example2.sh python-example.py
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 6.12: mv Rename

Command Summary

Command	Purpose
file [FILENAME]	Determines the file type of FILENAME
mkdir [DIRECTORY]	Make the directory DIRECTORY
cp [SOURCE] [DEST]	Copy the SOURCE TO DEST
cp -r [SOURCE] [DEST]	Copy the SOURCE directory recursively to the DEST
rm [FILENAME]	Remove or delete FILENAME
rm -r [DIRECTORY]	Remove or delete DIRECTORY recursively
mv [SOURCE] [DIRECTORY]	Move the SOURCE file or directory to DIRECTORY
mv [SOURCE] [DEST]	Rename the SOURCE file or directory to DEST

Chapter 7

File Permissions

Definitions

1. **File Permissions** - rights to access given files for specific users or groups
2. **Octal** - numeral system in base 8 comprised of the numbers 0 to 7

With the basic knowledge about files and how to manipulate them, the next step is to learn about file permissions. Every file has certain permissions that dictate which users can interact with the file and what type of interactions they can have.

Type of File Permissions

Files are assigned any three of the following permissions:

1. **Read**: allows a user to view the contents of a given file
2. **Write**: allows a user to modify the contents of a given file
3. **eXecute**: allows a user to run or execute a given file as a script or program

Every file has a combination of the three permissions. For example, let's say we create the file `myfile.txt`, this file could have read and write permissions, denoted by `rw-`. This means a user can read and write to the file, but cannot execute it. Another file named `script.sh` can have read-write-execute access, which is denoted by `rwx`. This means a user can read, write-to, and execute the file.

With the Linux operating system, files have Unix-style permissions. This means that file permissions are based on three categories:

1. Owner/user (**u**): the user who created/owns the file
2. Group (**g**): a specific group of users

3. Other (**o**): all other users

Note: The character in parentheses will be important later on when assigning permissions to specific categories

Reading File Permissions

Navigate to a directory that contains files. To view the permissions of the files in a directory, use the **ls** command with the additional argument **-l**. This argument displays the contents of the directory in long list format.. At the terminal, enter the command **ls -l**.

```

learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls -l
total 4
-rw-r--r-- 1 learninglinux learninglinux 48 Aug 14 09:57 myfile.txt
-rw-r--r-- 1 learninglinux learninglinux 0 Aug 14 08:10 MYFILE.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ █

```

Figure 7.1: Reading File Permissions

The very first line of the output is “total 4”. This is not relevant to file permissions, but it represents the total number of file system blocks all the files take up in this directory.

The next line contains information regarding **myfile.txt**.

1. **-rw-r-r-**: file permissions for **myfile.txt**
2. **learninglinux**: owner of the file
3. **learninglinux** (the second one): group
4. **48**: size of the file in bytes
5. **Aug 14 09:57**: date that the file was either created either or last modified
6. **myfile.txt**: name of the file

The file permissions have four distinct parts:

1. **-**: The first part is either a simple dash or the character **d**. The dash represents that it is a file, while a **d** represents a directory.
2. **rw-**: The next three characters are for the owner/user of the file. The owner can read and write to this file, but not execute it.
3. **r-**: The next set of three characters is for the group. Anyone in this group has permission to read the files only.

4. **r-:** The last set of three characters is for all other users. They can only read the file.

Another example demonstrates the different groups that could have access to a file or directory.

```
cbw@DESKTOP:~$ ls -l
drwxrwxrwx 0 cbw cbw      512 Jan 29 22:46 my_dir
-rw-rw-rw- 1 cbw cbw       17 Jan 29 22:46 my_file
-rwxrwxrwx 1 cbw faculty  313 Jan 29 22:47 my_program.py
-rw----- 1 root root    896 Jan 29 22:47 sensitive_data.csv
```

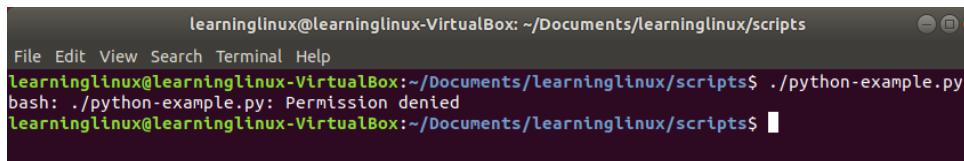

Figure 7.2: File Permissions with Groups

In the first and second listing, the owner and group are the same: “cbw”. However, with the third file, the owner is “cbw”, but the group is “faculty”. Any user that is part of the “faculty” group will have read-write-access to the file. The last file has a special set of permissions. Only the root user has access to this file.

Changing File Permissions - Basic

Changing file permissions allows you to either add or remove permissions from certain files.

There is a file in the scripts directory named `python-example.py`. Try to run this script from the terminal. Type `./example-python.py`. An error message appears and denies permission to run the script.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts". The window shows the following command and output:
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts\$./python-example.py
bash: ./python-example.py: Permission denied
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts\$ █

Figure 7.3: Permission Denied

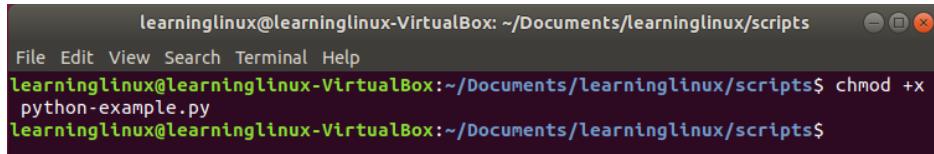

Now take a look at the file permissions for the script. Type `ls -l python-example.py` in the terminal. Adding the filename as an optional argument to the `ls` command applies the command to only the specified file instead of the entire directory.

The file permissions for the python script are: `-rw-r-r-`. This file has no execute permissions. That is why permission was denied.

To change file permissions, use the **chmod** command, which stands for change mode. There are multiple syntaxes for the command:

1. `chmod [OPTION] [MODE] [FILE]`
2. `chmod [OPTION] [OCTAL-MODE] [FILE]`

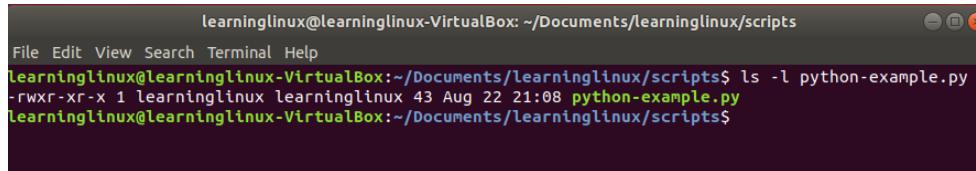

Type `chmod +x python-example.py`. The `+x` means to add permission to execute the file.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ chmod +x
python-example.py
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 7.4: Adding Execute Permissions

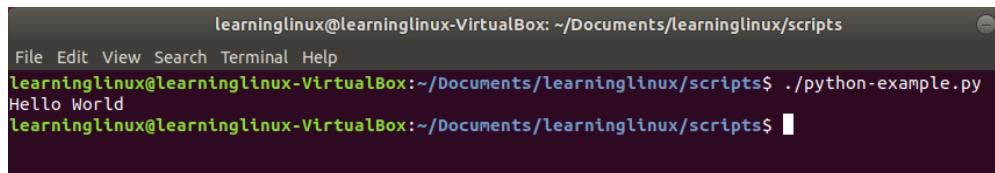

Look at the file permissions again using the `ls` command.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ ls -l python-example.py
-rwxr-xr-x 1 learninglinux learninglinux 43 Aug 22 21:08 python-example.py
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 7.5: Verifying the Permissions have been Added

Now the file permissions for the script are: `-rwx-r-xr-x`. All groups may now run this script. Run the program to see what it does. Type `./python-example.py`. It is a simple Hello World program.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ ./python-example.py
Hello World
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

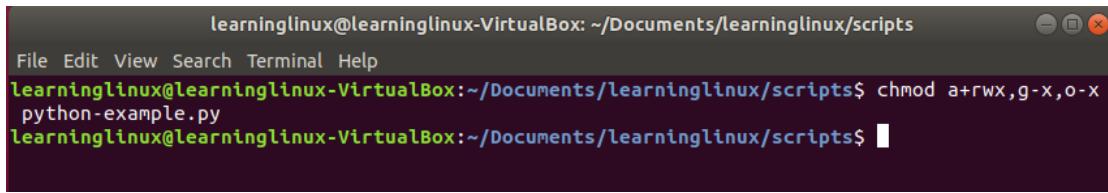

Changing File Permissions - Advanced

In the last example, adding the `+x` argument to the command added executable file permissions to all the different categories (owner, group, and other). That may not be desirable if the file permissions need to be restricted.

Type in the command `chmod a+rwx,g-x,o-x python-example.py`. Here is a breakdown of the command:

1. **a+rwx**: Give read-write-execute permissions to all three categories
2. **g-x**: Remove execute permissions from the group
3. **o-x**: Remove execute permissions from all other users

Now look at the permissions again using the `ls` command.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts". The window shows the command `chmod a+rwx,g-x,o-x python-example.py` being run, which changes the permissions of the file `python-example.py` to `-rwx-rw-rw`. The terminal window has a dark background with light-colored text.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts$ chmod a+rwx,g-x,o-x python-example.py
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts$
```

Figure 7.6: Advanced File Permissions

The file permission is now `-rwx-rw-rw`. Only the owner of the file has the ability to execute the file.

Changing File Permissions - Octal

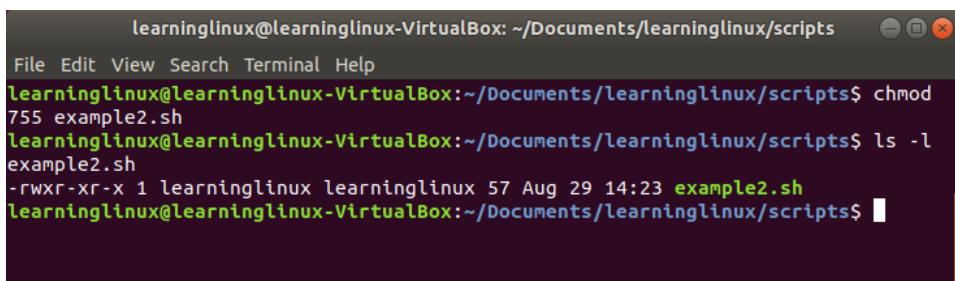

Another way to change file permissions is by using octal mode. Octal mode uses the octal numeral system, which is comprised of the numbers 0-7. Here is a breakdown of the octal numbers for file permissions.

1. **4:** gives read permissions
2. **2:** gives write permissions
3. **1:** gives execute permissions

As noted earlier, there are three categories: owner, group, and other users. Each of these categories has an assigned octal number. This means a three digit number assigns file permissions. The first number is for the owner, the second is for the group, and the last is for other users. To determine the number used for each category, sum the numbers of the associated file permissions. So if you want to give a category read-write-execute permissions, it would be $4 + 2 + 1 = 7$.

In the last example we gave read-write-execute permissions to the owner, and only read-write permissions to the group and other users. In octal mode, this would be 766, and the command would be `chmod 766 python-example.py`.

In the `scripts` directory, there is a script named `example2.sh`. This is a shell script that does not have an execute permission at the moment. Additionally, only the owner should be able to write to the script. Every other category can read and execute the script. With these criteria, the proper octal would be 755. Go to the terminal and type `chmod 755 example2.sh`.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts". The window shows the command `chmod 755 example2.sh` being run, which changes the permissions of the file `example2.sh` to `-rwxr-xr-x`. The terminal window has a dark background with light-colored text.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts$ chmod 755 example2.sh
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts$ ls -l
example2.sh
-rwxr-xr-x 1 learninglinux learninglinux 57 Aug 29 14:23 example2.sh
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts$
```

Figure 7.7: Octal Permissions

As a result of the command, the file permissions changed to `-rwxr-xr-x`, which is the desired outcome. To learn the different combinations of octal numbers for the chmod command, go to <http://chmodcommand.com>. This is a helpful website for beginners to learn chmod octal mode.

Command Summary

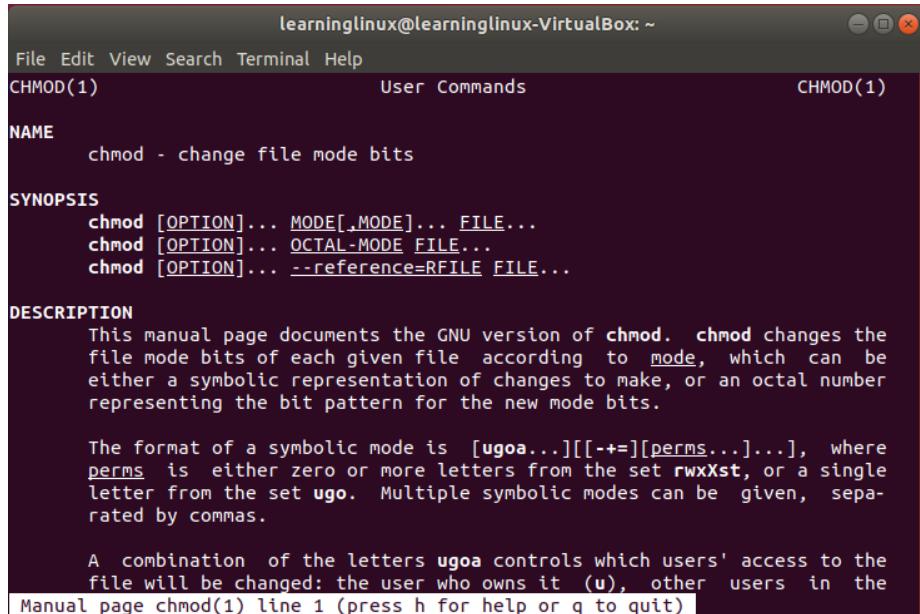

Command	Purpose
<code>ls -l [FILENAME]</code>	list FILENAME information in long format
<code>chmod [MODE] [FILE]</code>	change permissions to MODE for FILE
<code>chmod [OCTAL MODE] [FILE]</code>	change permission to OCTAL MODE for FILE

Chapter 8

Manual Pages

Manual pages are extremely helpful to learn the syntax and arguments for a command. Often, if you cannot run a command properly, the solution can be found on the manual page.

To display all of the optional arguments for a command and to see more information about that command, use the **man** command, which is short for manual. The syntax for the command is **man [COMMAND]**, where the command is what you want to see the manual page of. Go to your terminal and type in *man chmod*.

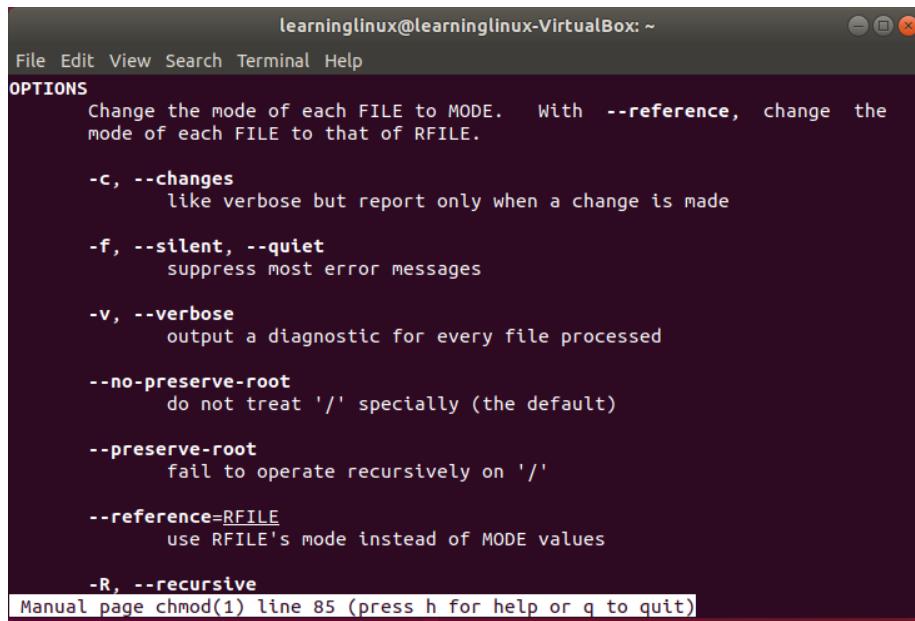

The screenshot shows a terminal window titled "learninglinux@learninglinux-VirtualBox: ~". The window title bar also displays "CHMOD(1)" and "User Commands". The terminal menu bar includes File, Edit, View, Search, Terminal, and Help. The main content area displays the man page for the chmod command. It starts with the NAME section, which describes chmod as "change file mode bits". The SYNOPSIS section shows three ways to use chmod: with symbolic options and modes, with octal modes, or with a reference file. The DESCRIPTION section provides a detailed explanation of what chmod does, mentioning it changes file mode bits and supports symbolic and octal representations. A note at the bottom explains the format of symbolic modes and how they control access. A status bar at the bottom right indicates "Manual page chmod(1) line 1 (press h for help or q to quit)".

Figure 8.1: Manual Page for chmod

The below are parts of the manual pages for the **chmod** command. All man pages follow the following common format:

1. **Name** – the name of the command and a short description

2. **Synopsis** – summary of the command with its syntax
3. **Description** – description of the command
4. **Options** – list of optional arguments for the command and their descriptions
5. **See Also** – related commands and link to full documentation online

```
learninglinux@learninglinux-VirtualBox: ~
File Edit View Search Terminal Help
OPTIONS
    Change the mode of each FILE to MODE.  With --reference, change the
    mode of each FILE to that of RFILE.

    -c, --changes
        like verbose but report only when a change is made

    -f, --silent, --quiet
        suppress most error messages

    -v, --verbose
        output a diagnostic for every file processed

    --no-preserve-root
        do not treat '/' specially (the default)

    --preserve-root
        fail to operate recursively on '/'

    --reference=RFILE
        use RFILE's mode instead of MODE values

    -R, --recursive
Manual page chmod(1) line 85 (press h for help or q to quit)
```

Figure 8.2: Options Part of Manual Pages

Figure 8.3: Misc Details in Manual Pages

Once you are done with the man page, press “q” to get back to the terminal.

Searching the Manual Pages

If you are unsure of which command to use, you can perform a general search on all of the manual pages to see which ones contain a particular keyword. To do this, use the **man** command with the optional argument **k**, followed by the keyword that you are searching for.

Go to the terminal and type in *man -k sort*.

```
learninglinux@learninglinux-VirtualBox:~$ man -k sort
apt-sortpkgs (1)      - Utility to sort package index files
bunzip2 (1)            - a block-sorting file compressor, v1.0.6
bzip2 (1)              - a block-sorting file compressor, v1.0.6
comm (1)               - compare two sorted files line by line
sort (1)               - sort lines of text files
tsort (1)              - perform topological sort
XConsortium (7)        - X Consortium information
learninglinux@learninglinux-VirtualBox:~$
```

Figure 8.4: Searching the Manual Pages

This search returns a list of all the commands that mention the term “sort”. Searching the man pages by keyword is often underutilized, but it is extremely helpful to find the desired command.

Command Summary

Command	Purpose
man [COMMAND]	displays the manual page for COMMAND
man -k [KEYWORD]	searches all the manual pages for the KEYWORD

Chapter 9

Complex Inputs

Definitions

1. **Complex Input** - input containing characters other than the standard English alphabet and numbers
2. **Wildcard** - characters that are used to substitute unknown characters in a search
3. **Escape Character** - a character that changes the interpretation of the subsequent character

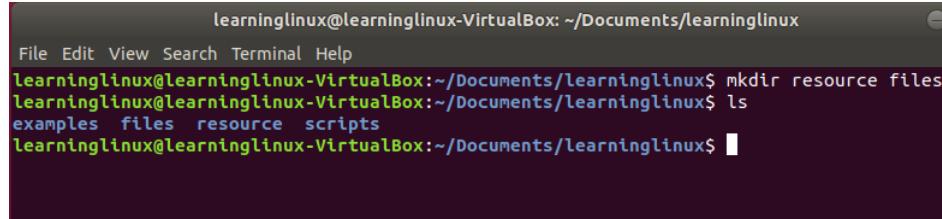

Complex Input

So far all of the commands that have been introduced use input that contains only alphanumeric characters. However, commands also use and interpret complex inputs, which contain wildcards, escape characters, whitespace, or text enclosed in quotes. Examples of complex inputs are as follows:

1. *.txt
2. myfile.???
3. “Hello World”
4. \n
5. \t
6. '\$PATH'

Spaces (Whitespace)

Spaces are often the most overlooked complex input. In the shell, whitespace indicates the end of an argument or command and the shell splits the commands and arguments accordingly. A common issue that can occur is moving into a directory whose name contains a space.

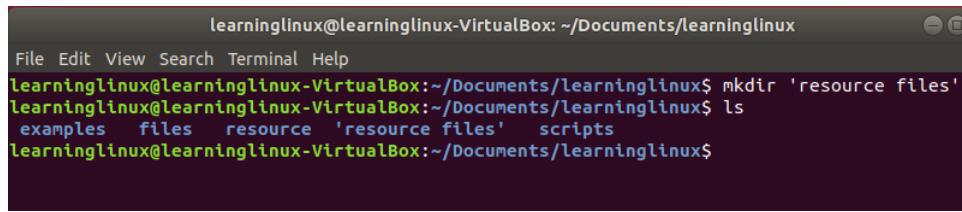

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ mkdir resource files
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples files resource scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 9.1: `mkdir` Without Whitespace

For example, you wish to create a single folder named `resource files`. If you use the command `mkdir resource files`, the shell interprets two separate names and creates two new directories.

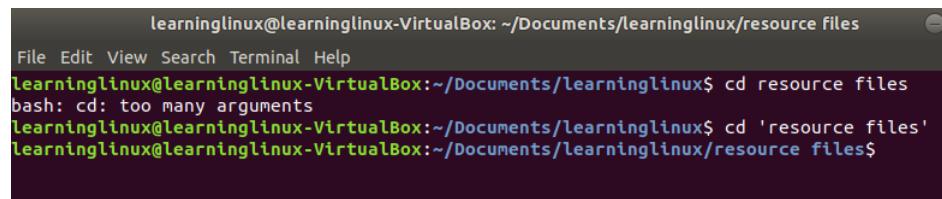

The proper way to make a directory (or file) that contains a space is to put the name in quotes. Go to the terminal and type `mkdir 'resource files'`.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ mkdir 'resource files'
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ ls
examples files resource 'resource files' scripts
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$
```

Figure 9.2: `mkdir` With Whitespace

Another issue that occurs with directory (or file) names that contain spaces is with the `cd` command. Type `cd resource files` in the terminal, and it displays an error. To avoid the problem, enclose the directory name in quotes: `cd 'resource files'`.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/resource files
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cd resource files
bash: cd: too many arguments
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux$ cd 'resource files'
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/resource files$
```

Figure 9.3: `cd` With Whitespace

Note: Avoid using spaces in filenames or directory names. This makes it difficult to perform operations on such files and directories.

Quoting (Strong & Weak)

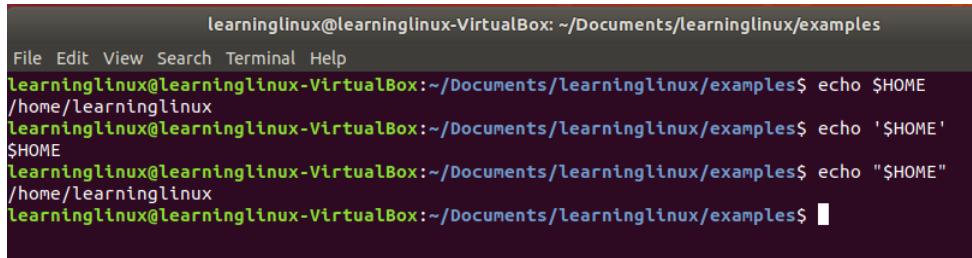

Quoting is a method of encapsulation that allows the shell to interpret commands and arguments that may have spaces, other complex inputs, or special characters reserved for the shell. There are two types of quoting:

1. **Strong Quoting** - uses the single quote, and interprets everything literally (as it is)
2. **Weak Quoting** - uses the double quote, and the shell will evaluate variables

To see the differences between strong and weak quoting, use the **echo** command. The syntax for this command is **echo [STRING]**. The command will display the string to the standard output. Go to the terminal and type **echo \$HOME**. The **\$HOME** is a special variable in the shell that is reserved for the home directory. This command will display the home directory on the command line.

Now try the command **echo '\$HOME'**. This time, **\$HOME** is enclosed by single quotes and the result is different. The output is the string '**\$HOME**'. Since single quotes are used here, the shell interprets the string literally and does not expand it.

Lastly, try the command **echo "\$HOME"**. This displays the home directory as in the first example. Since double quotes are used, the shell will expand the variable and output the expansion to the command line.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ echo $HOME
/home/learninglinux
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ echo '$HOME'
$HOME
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ echo "$HOME"
/home/learninglinux
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ █
```

Figure 9.4: Strong and Weak Quoting Examples

Wildcards

Wildcards are characters used as substitutes for one or more characters in a search, giving the search more flexibility. Three types of wildcards are used in a Linux environment:

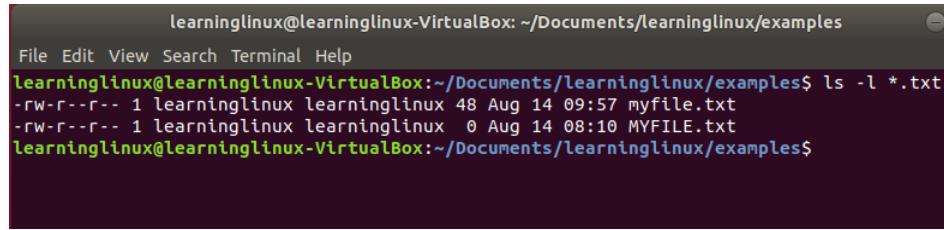

1. * (star wildcard)
2. ? (question mark wildcard)
3. [] (square brackets wildcard)

When a command uses a wildcard, the shell will interpret the wildcard, perform the query, and then use the results to execute the rest of the command.

Star Wildcard

The star wildcard is the asterisk. This is the most versatile wildcard. It can represent any number of characters. Navigate to a directory that contains text files and run the command **ls -l *.txt**. This command will

search for any file or directory in the directory with an ending of .txt. The shell will transform this to *ls -l myfile.txt MYFILE.txt*.

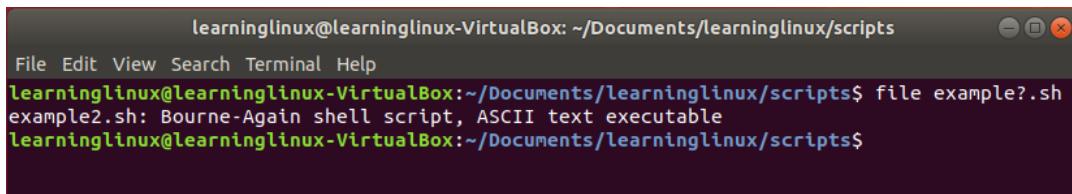

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ ls -l *.txt
-rw-r--r-- 1 learninglinux learninglinux 48 Aug 14 09:57 myfile.txt
-rw-r--r-- 1 learninglinux learninglinux 0 Aug 14 08:10 MYFILE.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$
```

Figure 9.5: Star Wildcard

Question Mark Wildcard

The next wildcard is the question mark (?). This wildcard represents only one character. Navigate to the scripts directory and type in the command *file example?.sh*. The shell transforms this to *file example2.sh*.

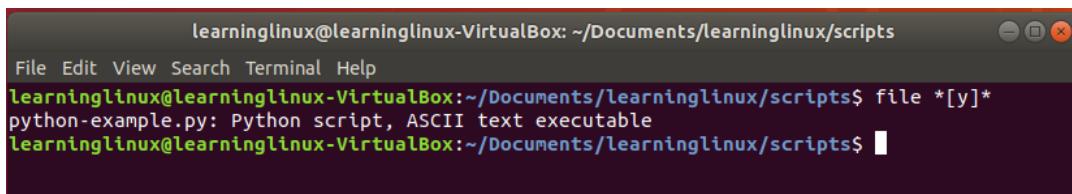

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ file example?.sh
example2.sh: Bourne-Again shell script, ASCII text executable
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 9.6: Question Mark Wildcard

Square Brackets Wildcard

The last wildcard are the square brackets ([]). This wildcard substitutes all the characters that are enclosed within the brackets. In the same scripts directory, type in the command *file *[y]**. This command will search for anything in the directory that contains the character y. The shell transforms the command to *file python-example.py*.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/scripts
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$ file *[y]*
python-example.py: Python script, ASCII text executable
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/scripts$
```

Figure 9.7: Square Brackets Wildcard

Escape Characters

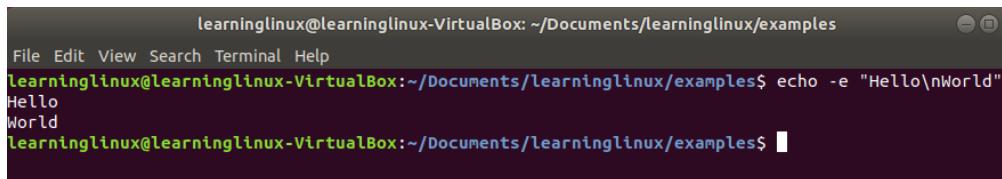

Escape characters are important when using the command line because they change the meaning of the next sequence of characters so that the shell interprets them in a particular manner.

The following are commonly used escape characters.

Escape Character	Interpretation
\"	double-quote
\'	single-quote
\n	newline
\t	horizontal tab
\b	backspace

Earlier there was an issue with spaces in the name of a directory. Recall the command: *mkdir 'resource files'*. The name of the directory was enclosed in single quotes so that the shell could interpret the name of the directory properly. However, an alternative command could be used: *mkdir resource files*. In this command, the escape character is “ \ ”, which is a backslash followed by a space. When this command is processed, the shell will interpret the escape character as a space and therefore, the directory name does not need to be enclosed in quotes.

A simple example of an escape character used in a command can be shown by using the echo command again. Try the command *echo -e "Hello\nWorld"*. The e argument allows the echo command to interpret escape characters.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/examples
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$ echo -e "Hello\nWorld"
Hello
World
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/examples$
```

Figure 9.8: Escape Characters

Command Summary

Command	Purpose
echo [STRING]	displays the STRING to the standard output

Chapter 10

Process Management

Definitions

1. **Process** - a program that is being executed
2. **Foreground Process** - process that is active in the terminal and may require additional input
3. **Background Process** - process that runs without being connected to an input source

Foreground and Background Processes

There are two ways to run a process, either in the foreground or in the background. A foreground process takes input from the keyboard and outputs to the screen or terminal. All of the commands so far have been processes that run in the foreground.

A background process operates without being connected to the keyboard. If a background process requires input, it will wait for the input. If a process runs in the background, then other commands and processes can be started from the terminal and they do not need to wait for the background process to complete. To have a process run in the background, put an ampersand (&) symbol at the end of a command. An example of this is provided later in this section.

Process States

A process state changes over time as the Linux environment changes. There are four process states in Linux:

1. **Running** - current process in the system or waiting to be assigned to a CPU
2. **Waiting** - process is waiting for system resources or for an event to occur
3. **Stopped** - process is not running
4. **Zombie** - process has been completely halted, but still has an entry in the process table

Viewing Active Process

Two commands can be used to view the active processes on the machine: **ps** and **top**. **ps** stands for process status. The syntax for this command is **ps [OPTIONS]**. There are many optional arguments for this command and they can be used in various combinations. Go to the terminal and type *ps*.

```
learninglinux@learninglinux-VirtualBox:~$ ps
  PID TTY      TIME CMD
 3277 pts/0    00:00:00 bash
 3290 pts/0    00:00:00 ps
learninglinux@learninglinux-VirtualBox:~$
```

Figure 10.1: **ps** Command

The output displays four columns of information:

1. **PID** - the process ID; each process is assigned a unique number
2. **TTY** - terminal type associated with the process
3. **TIME** - CPU time used by the process
4. **CMD** - the command that started the process

Some additional arguments that can be added to the **ps** command are **e** and **f**. The **e** argument will list all the processes in the system and the **f** argument shows all the information about the process. Try the command **ps -ef** in the terminal.

UID	PID	PPID	C	STIME	TTY	TIME	CMD
root	1	0	0	22:53	?	00:00:02	/sbin/init splash
root	2	0	0	22:53	?	00:00:00	[kthreadd]
root	4	2	0	22:53	?	00:00:00	[kworker/0:0H]
root	6	2	0	22:53	?	00:00:00	[mm_percpu_wq]
root	7	2	0	22:53	?	00:00:00	[ksoftirqd/0]
root	8	2	0	22:53	?	00:00:00	[rcu_sched]
root	9	2	0	22:53	?	00:00:00	[rcu_bh]
root	10	2	0	22:53	?	00:00:00	[migration/0]
root	11	2	0	22:53	?	00:00:00	[watchdog/0]

Figure 10.2: **ps -ef** Command

There is more output than is displayed in the picture above. There are now eight columns of information for each process:

1. **UID** – user ID of the person who ran the process

2. **PID** – [SAME AS ABOVE]

3. **PPID** – parent process ID, the ID of the process that started this process

4. **C** – CPU utilization of the process

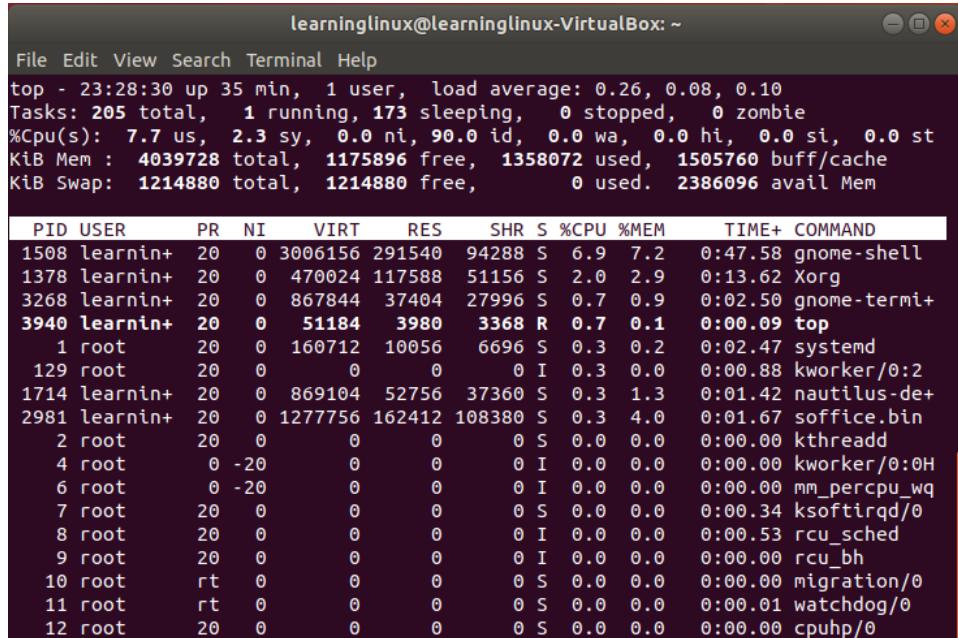

5. **STIME** – time that the process was started

6. **TTY** – [SAME AS ABOVE]

7. **TIME** – [SAME AS ABOVE]

8. **CMD** – [SAME AS ABOVE]

The other command to view active processes is **top**. The syntax for the command is **top [OPTIONS]**. Go to the terminal and type *top*.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~". The window displays the output of the "top" command. The top part shows system statistics: tasks (205 total), CPU usage (%Cpu(s)), memory usage (KiB Mem and Swap), and a header for the process list. The bottom part is a table showing the top 12 processes. The columns are: PID, USER, PR, NI, VIRT, RES, SHR, S, %CPU, %MEM, TIME+, and COMMAND. The processes listed include gnome-shell, Xorg, gnome-terminal, top, systemd, kworker, nautilus, soffice.bin, kthreadd, kworker, mm_percpu_wq, ksoftirqd, rCU_sched, rCU_bh, migration, watchdog, and cpuhp.

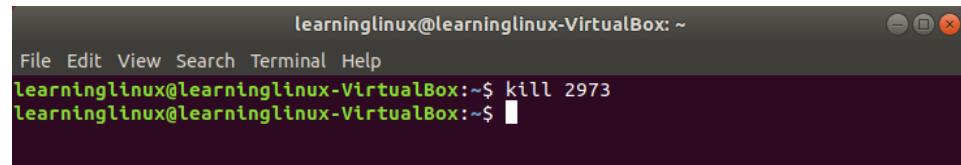

PID	USER	PR	NI	VIRT	RES	SHR	S	%CPU	%MEM	TIME+	COMMAND
1508	learnin+	20	0	3006156	291540	94288	S	6.9	7.2	0:47.58	gnome-shell

12	root	20	0	0	0	0	S	0.0	0.0	0:00.00	cpuhp/0

Figure 10.3: top Command

Killing Processes

If a process has frozen and becomes unresponsive, you may have to end it. To end a process, use the **kill** command. The syntax for this command is **kill [OPTIONS] [PID]**. To kill a process, the process id (pid) must be known, and that is how the operating system knows which process to end.

For example, say Firefox was opened, but became unresponsive and had to be killed through the command line. First, run the **ps** command to locate the pid number for the Firefox process. The next section will explain how to find the pid quickly without having to read all the output of **ps**. Upon a quick search, the pid is 2973. Then type in the terminal *kill 2973*.

```
learninglinux@learninglinux-VirtualBox:~$ kill 2973
learninglinux@learninglinux-VirtualBox:~$
```

Figure 10.4: kill Command

If the ps command is run again, no process should be listed relating to Firefox.

Now if there are multiple processes that are frozen, unresponsive, or that are replicating at an exponential rate, there is a command to end all processes. That command is pkill. The syntax for this command is `pkill -u [USERNAME]`. Applying the optional `u` argument along with the username will kill **ALL** processes that were started by the user.

A lot of my processes such as Firefox, word processor, and the file explorer are now unresponsive and I want to end all of them. To do so, I would type in my terminal: `pkill -u learninglinux`.

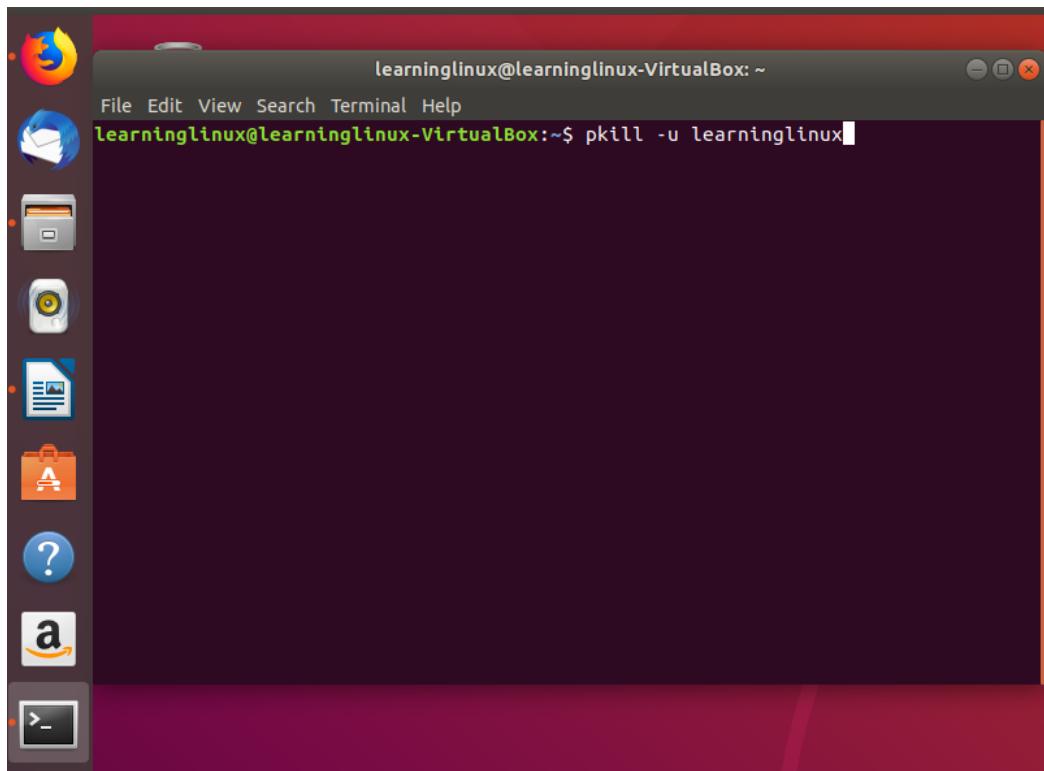

Figure 10.5: pkill Command Before

After executing this command, none of the programs are running, and the terminal was stopped as well.

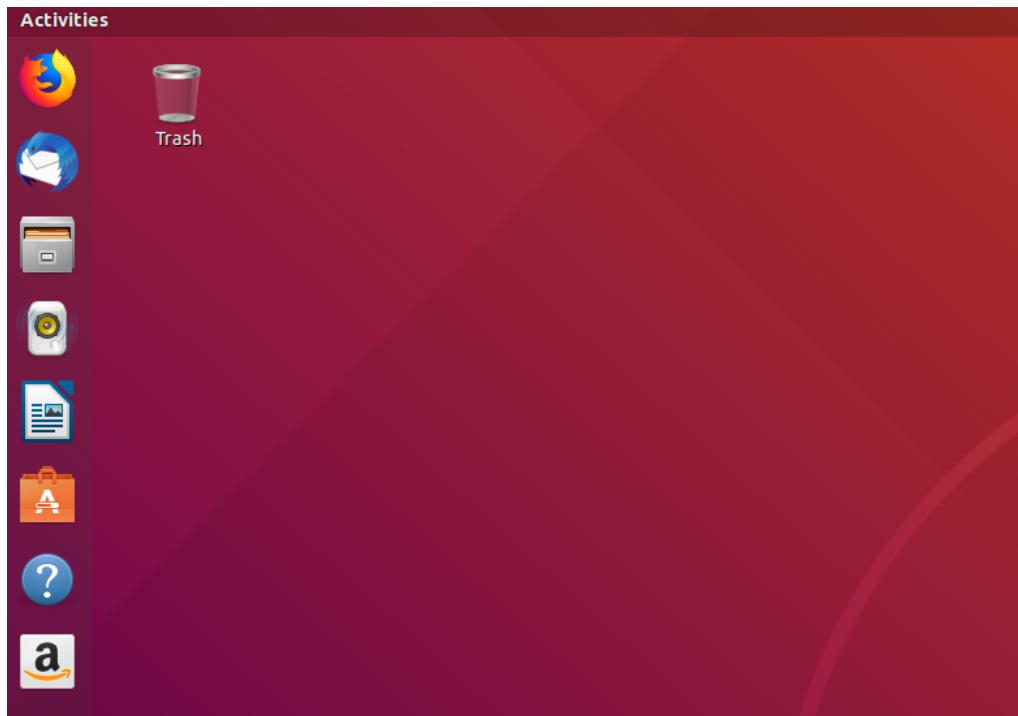

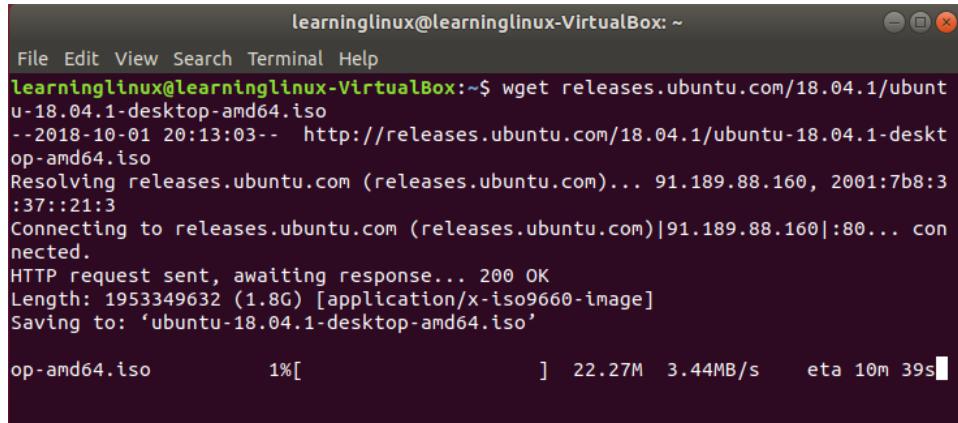

Figure 10.6: pkill Command After

Moving Processes To and From the Background and Foreground

Running processes in the background can be convenient because you can still use the command line while the process runs. For example, downloading a file from the command line will display the progress of the download, but this may be time consuming. The command to download a file is **wget**. The syntax for this command is `wget [URL]`. The command `wget releases.ubuntu.com/18.04/l/ubuntu-18.04.1-desktop-amd64.iso` will download the operating system file for Ubuntu 18.04 LTS. This is a large file and this download would take at least 10 min.

Warning: Do not try this command in the terminal

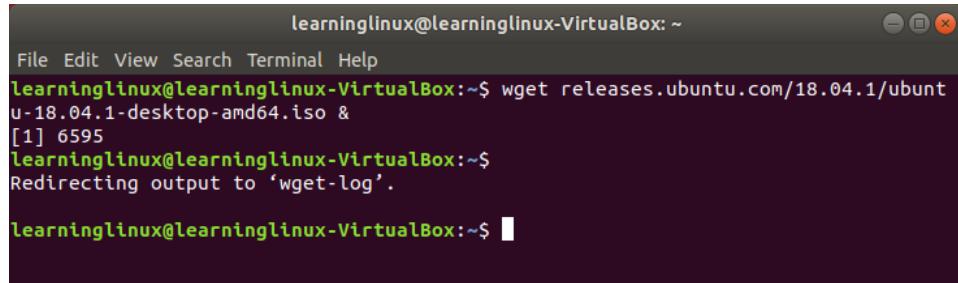

```
learninglinux@learninglinux-VirtualBox:~$ wget releases.ubuntu.com/18.04.1/ubuntu-18.04.1-desktop-amd64.iso
--2018-10-01 20:13:03-- http://releases.ubuntu.com/18.04.1/ubuntu-18.04.1-desktop-amd64.iso
Resolving releases.ubuntu.com (releases.ubuntu.com)... 91.189.88.160, 2001:7b8:3:37::21:3
Connecting to releases.ubuntu.com (releases.ubuntu.com)|91.189.88.160|:80... connected.
HTTP request sent, awaiting response... 200 OK
Length: 1953349632 (1.8G) [application/x-iso9660-image]
Saving to: 'ubuntu-18.04.1-desktop-amd64.iso'

ubuntu-18.04.1-desktop-amd64.iso      1%[          ]  22.27M  3.44MB/s    eta 10m 39s
```

Figure 10.7: wget Command

During the download, the terminal cannot be used since it displays the progress of the download in the foreground. However, by moving the process to the background, the command line can be used to do other things as the file is being downloaded. To have a process run in the background, add the ampersand (&) symbol directly after the command. Now the command would be `wget releases.ubuntu.com/18.04.1/ubuntu-18.04.1-desktop-amd64.iso &`.

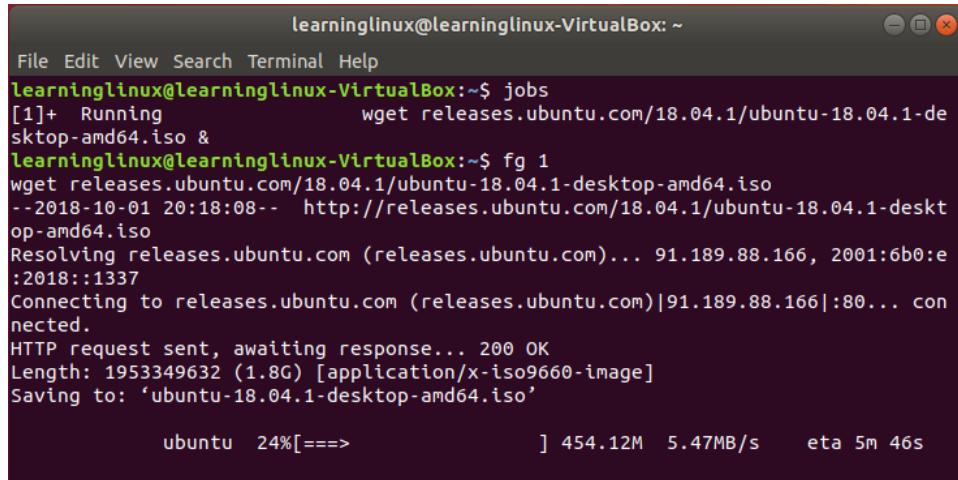

```
learninglinux@learninglinux-VirtualBox:~$ wget releases.ubuntu.com/18.04.1/ubuntu-18.04.1-desktop-amd64.iso &
[1] 6595
learninglinux@learninglinux-VirtualBox:~$ Redirecting output to 'wget-log'.
```

Figure 10.8: wget Background

The process is running in the background now and will continue to run until it is complete or it is stopped by the operating system.

To view the processes that are running in the background, use the **jobs** command. The following is the output of the **jobs** command and the download status is moved to the foreground.

The screenshot shows a terminal window with a dark background and light-colored text. At the top, the window title is "learninglinux@learninglinux-VirtualBox: ~". The menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". Below the menu, the command "jobs" is run, showing a single job [1] running a wget command to download an ISO file. Then, "fg 1" is run to move this job to the foreground. The wget progress is shown with a bar indicating 24% completion at a rate of 5.47MB/s, estimated to finish in 5m 46s.

```

learninglinux@learninglinux-VirtualBox:~$ jobs
[1]+  Running                  wget releases.ubuntu.com/18.04.1/ubuntu-18.04.1-de

```

Figure 10.9: jobs Command

To move the most recent background process to the foreground, use the **fg** command. The other way to move a process back to the foreground is to specify the job number as an argument. The **jobs** command displays the **job** number associated with a background process.

Command Summary

Command	Purpose
ps [OPTIONS]	displays all the active processes
top	displays all the active processes
kill [PID]	kill the process with the given PID
pkill -u [USERNAME]	kills all processes started by USERNAME
wget [URL]	downloads a file from the URL
jobs	displays the status of all the current jobs
fg	moves the most recent job to the foreground

Chapter 11

Filters and Regular Expressions

Definitions

1. **Regular Expression** - sequence of characters that define a search pattern

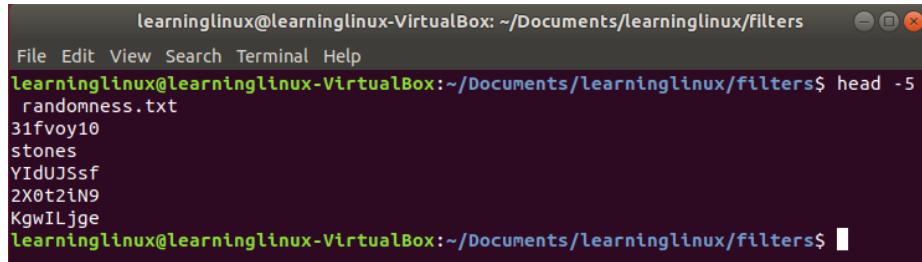

Filtering

Filtering allows you to search through data in specified ways. There are basic filtering techniques such as getting the first five items of a list, or sorting the items alphabetically. Advanced filtering techniques make use of regular expressions (regex) in order to search for very specific data items.

The examples in this section make use of a file called `randomness.txt`, which includes 25 alphanumeric strings, some of which are words.

Head

The **head** command outputs the first n number of lines. The syntax for this command is `head [OPTIONS] [FILE]`. To see the first 5 lines of the `randomness.txt` file, go to the terminal and type in `head -5 randomness.txt`

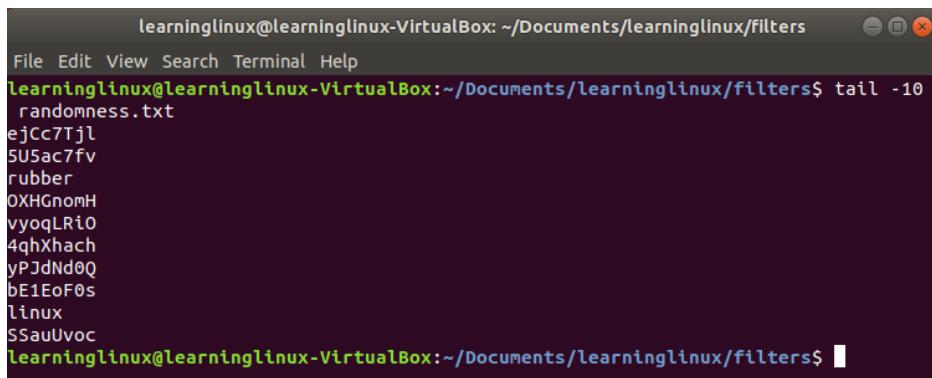

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ head -5
randomness.txt
31fvoY10
stones
YIdUJssf
2X0t2iN9
KgwILjge
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.1: head Command

The output is the first five lines of the file.

Tail

The **tail** command is just like the **head** command, but it will output the last n number of lines. The syntax for the **tail** command is `tail [OPTIONS] [FILE]`. To see the last 10 lines of the `randomness.txt` file, go to the terminal and type in `tail -10 randomness.txt`.

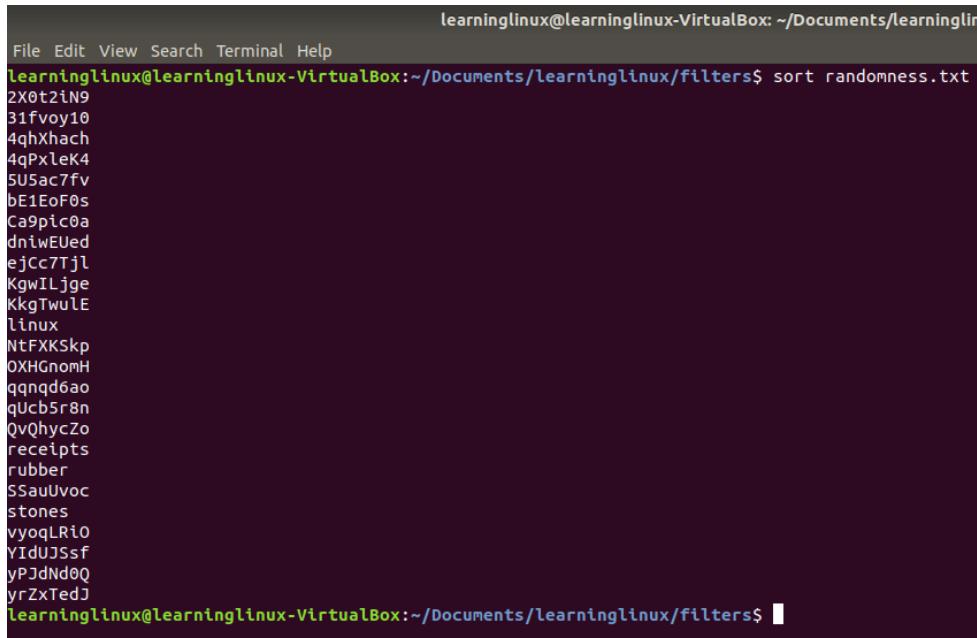

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ tail -10
randomness.txt

vyoqLRiO
4qhXhach
yPJdNd0Q
be1EoF0s
linux
SSauUvoc
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.2: tail Command

The output is the last 10 lines of the `randomness.txt` file.

Sorting

Sorting is a powerful filtering technique used in many algorithms and applications. To sort the contents of a file, use the **sort** command. The syntax is **sort [OPTIONS] [FILE]**. To sort the **randomness.txt** file, go to the terminal and type in **sort randomness.txt**.

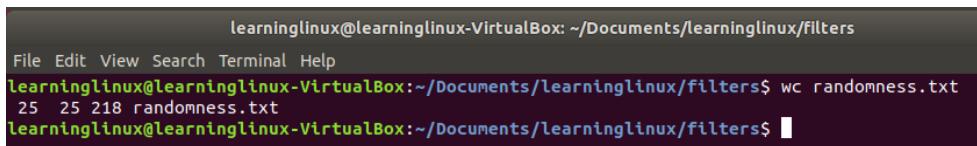

```
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ sort randomness.txt
2X0t2iN9
31fvoy10

yPJndd0Q
yrZxTedJ
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.3: sort Command

By default the **sort** command will sort in alphabetical order, but additional arguments can be specified in the command to sort by different categories.

Word Count

Another filtering technique is to get the word count of a file. To do this, use the **wc** command, which stands for word count. The syntax for the **wc** command is **wc [OPTIONS] [FILE]**. To get the word count of the **randomness.txt** file, go to the terminal and type in **wc randomness.txt**.

```
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ wc randomness.txt
25 25 218 randomness.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.4: wc Command

The output displays the number of words, which is 25; it also displays the number of characters in the file as well.

Unique Items

In some cases, there may be duplicate items in a data set. To search for the unique items in a data set, use the **uniq** command, which stands for unique. The syntax for this command is **uniq [OPTIONS] [INPUT]**. Go to the terminal and type in *uniq randomness.txt*.

```

learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters
File Edit View Search Terminal Help
Learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ uniq randomness.txt

linux
SSauUvoc
Learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ █

```

Figure 11.5: uniq Command

The output is all the strings in the file minus any repeated lines. However, it can be difficult to determine if any lines have been omitted or not. This can be easily done with piping which is discussed in the next chapter.

Regular Expressions

A regular expression, also called regex, is a combination of wildcards and other information which builds a particular search pattern. Regex is a powerful filtering tool, but it is often difficult to understand. Only a few basic examples are covered in this section.

Regex Syntax

The following are the various characters that are used in a regex:

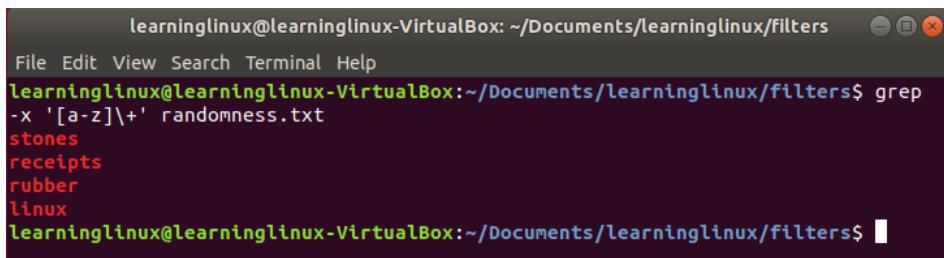

1. . (dot) – a single character
2. ? - preceding character matches zero or one times
3. * - preceding character matches zero or more times
4. + - preceding character matches one or more times
5. [a-z] – character is included in the range of characters specified by the brackets
6. [^ a-z] – character is not one of those included in the brackets in that range

7. {n} – preceding character matches exactly n times
8. {n, m} – preceding character matches at least n times, but not more than m times
9. ^ – matches at the beginning of the line
10. \$ – matches at the end of the line

The above can be combined in various ways in order to build the desired pattern.

Several different commands can use regex in order to find a matching pattern. For all the following examples, we use the **grep** command, which stands for global regular expression print. The syntax of this command is **grep [OPTIONS] PATTERN [FILE]**.

For the first example, we try to find words that only contain lowercase letters. The regex for this would be '`[a-z]\+>`'. `[a-z]` covers all the lowercase letters in the alphabet and the `\+` will match at least one or more lowercase letter. Now, the grep command would be `grep -x '[a-z]\+' randomness.txt`. Pay attention to the `x` optional argument. This will search entire lines instead of individual characters.

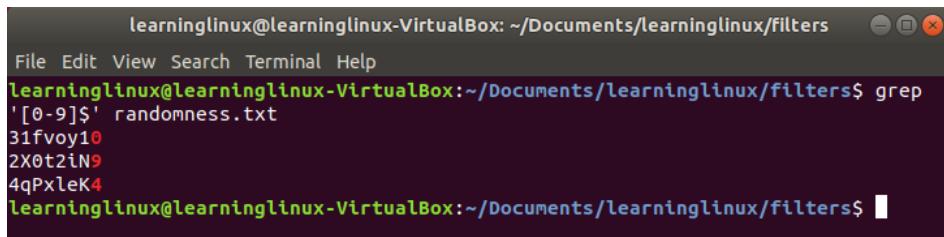

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ grep
-x '[a-z]\+' randomness.txt
stones
receipts
rubber
linux
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.6: Basic alphabetical grep search

As seen in the output above, only the words with all lowercase letters are displayed.

For the next example, we try to search for lines that end with a number. The regex for this would be '`[0-9]$`'. The `[0-9]` represents all the numbers, and the `'$'` matches the end of the line for the numbers. Now, the **grep** command would be `grep '[0-9]$' randomness.txt`.

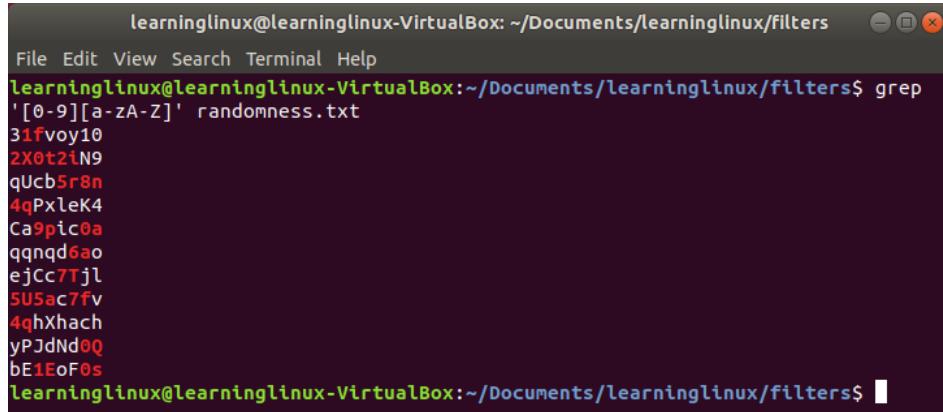

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$ grep
'[0-9]$' randomness.txt
31fvoy10
2X0t2iN9
4qPxeK4
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/filters$
```

Figure 11.7: Basic numeric grep search

As seen in the output above, there are three lines that end in a number.

For the last example, we will try to find the lines that have a number followed by a letter. The regex for this would be '[0-9] [a-zA-Z]'. The [0-9] represents the numbers and the [a-zA-Z] represents all upper and lowercase letters. The grep command would be *grep '[0-9][a-zA-Z]' randomness.txt*.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters$ grep '[0-9][a-zA-Z]' randomness.txt
31fvoy10
2X0t21N9
qUcb5r8n
4qPxleK4
Ca9pic0a
qqnqd6ao
ejcc7Tjl
5U5ac7fv
4ghXhach
yPJdNd0Q
bE1EoF0s
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/filters$
```

Figure 11.8: Advanced Grep Search

Command Summary

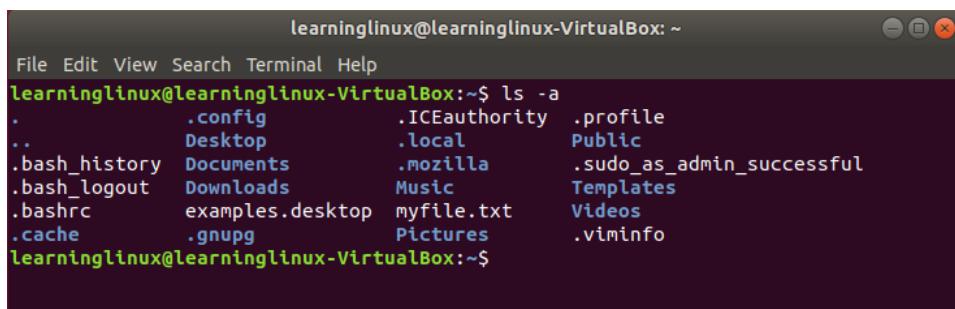

Command	Purpose
head [OPTIONS] [FILE]	return lines from the beginning of the FILE
tail [OPTIONS] [FILE]	return lines from the end of the FILE
sort [OPTIONS] [FILE]	sort the lines of FILE alphabetically
uniq [OPTIONS] [INPUT]	return non-repeating lines from the INPUT
wc [OPTIONS] [FILE]	give the word count of FILE
grep [OPTIONS] PATTERN [FILE]	search for the PATTERN in the lines of FILE

Input Output Redirection

Input & Output

Many of the examples used throughout the sections take advantage of inputting a command and awaiting for a particular output. These input and output are known as data streams, which can take many forms.

A screenshot of a terminal window titled "learninglinux@learninglinux-VirtualBox: ~". The window has a standard Linux-style title bar with icons for minimize, maximize, and close. The menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". The command prompt is "learninglinux@learninglinux-VirtualBox:~\$". The user runs the command "ls -a", which lists all files and directories in the current directory (~). The output shows a variety of file types and names, including ".config", ".ICEauthority", ".profile", ".local", "Public", ".bash_history", "Documents", ".mozilla", ".sudo_as_admin_successful", ".bash_logout", "Downloads", "Music", "Templates", ".bashrc", "examples.desktop", "myfile.txt", "Videos", ".cache", ".gnupg", "Pictures", ".viminfo". The terminal window has a dark background with light-colored text and a red border.

Figure 12.1: Input & Output Basic Example

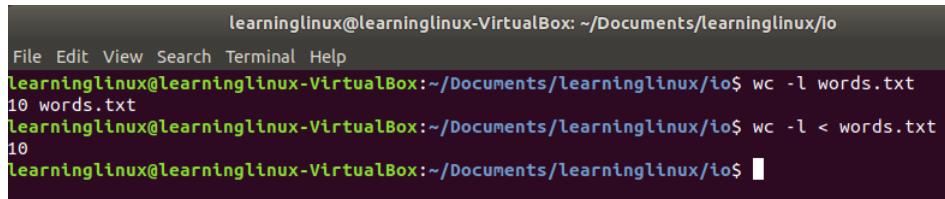

In this example, the input is the command `ls -a`, which is taken from the keyboard. And the output displays a list of all the files and directories in the terminal.

These data streams can be put into three categories:

1. **Standard Input** (`stdin`): input fed into the program, defaults to the keyboard
2. **Standard Output** (`stdout`): output of the program, defaults to the terminal
3. **Standard Error** (`stderr`): error messages of the program, defaults to the terminal

Redirecting Input

Commands can take input from a source other than the keyboard by using the “<” symbol. To determine the number of lines in a file, use the **wc** command. The syntax for this command is **wc [FILE] [OPTIONS]**. Type in **wc -l words.txt** in the terminal. This will output the number of lines in the file and the filename.

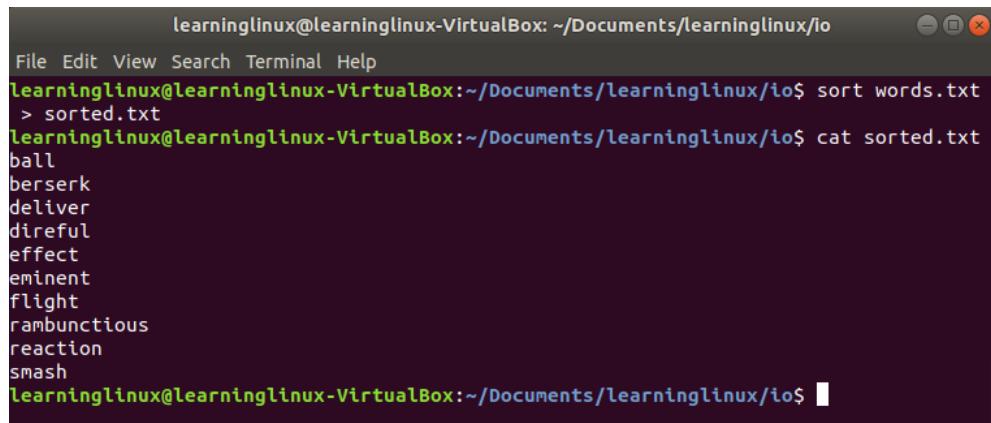

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/io
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$ wc -l words.txt
10 words.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$ wc -l < words.txt
10
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$
```

Figure 12.2: Redirecting Input

Now, type in **wc -l < words.txt**. The output is just 10. That is because the **wc** command uses input redirect from the file, and therefore does not know the filename.

Redirecting Output

Commands can redirect their output to places other than the terminal. For example, instead of outputting the results directly to the terminal, they can be put in a file. To redirect the output, use the “>” and then specify where the output should go. To sort ten words and put all the sorted words in a file, use the **sort** command. Type in the command **sort words.txt > sorted.txt**. This will sort all the words in the words.txt file and put the results in the sorted.txt file.

```
learninglinux@learninglinux-VirtualBox: ~/Documents/learninglinux/io
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$ sort words.txt
> sorted.txt
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$ cat sorted.txt
ball
berserk
deliver
direful
effect
eminent
flight
rambunctious
reaction
smash
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$
```

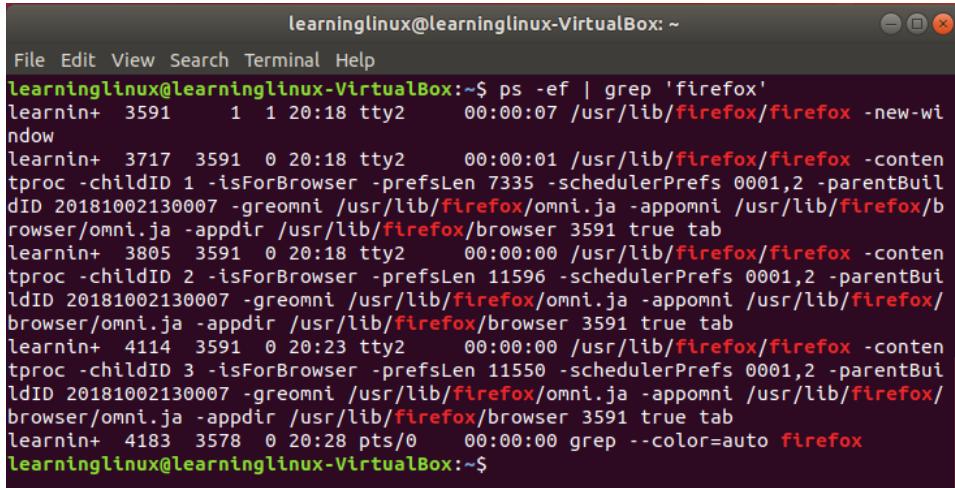

Figure 12.3: Redirecting Output

Then use the **cat** command to view the sorted words. Type in **cat sorted.txt**.

Piping and Command Chaining

Piping redirects the output of one command to the input of another command. Piping is very powerful because it enables you to use several commands without having to save the output to temporary files and such.

In the process management chapter, we had to parse through the output of the command `ps -ef` in order to find the process ID of a certain program that was running in order to kill the program. Using pipes streamlines this process even further. Try the command `ps -ef | grep 'firefox'`.

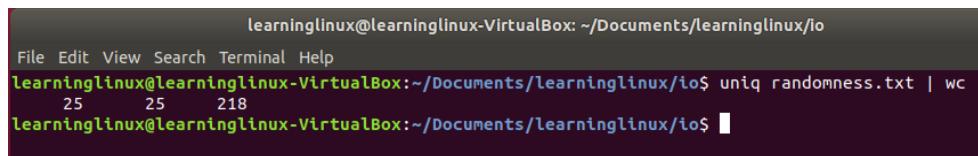

```
learninglinux@learninglinux-VirtualBox:~$ ps -ef | grep 'firefox'
learnin+ 3591 1 20:18 tty2 00:00:07 /usr/lib/firefox/firefox -newwindow
learnin+ 3717 3591 0 20:18 tty2 00:00:01 /usr/lib/firefox/firefox -contentproc -childID 1 -isForBrowser -prefsLen 7335 -schedulerPrefs 0001,2 -parentBuildID 20181002130007 -greomni /usr/lib/firefox/omni.ja -appomni /usr/lib/firefox/browser/omni.ja -appdir /usr/lib/firefox/browser 3591 true tab
learnin+ 3805 3591 0 20:18 tty2 00:00:00 /usr/lib/firefox/firefox -contentproc -childID 2 -isForBrowser -prefsLen 11596 -schedulerPrefs 0001,2 -parentBuildID 20181002130007 -greomni /usr/lib/firefox/omni.ja -appomni /usr/lib/firefox/browser/omni.ja -appdir /usr/lib/firefox/browser 3591 true tab
learnin+ 4114 3591 0 20:23 tty2 00:00:00 /usr/lib/firefox/firefox -contentproc -childID 3 -isForBrowser -prefsLen 11550 -schedulerPrefs 0001,2 -parentBuildID 20181002130007 -greomni /usr/lib/firefox/omni.ja -appomni /usr/lib/firefox/browser/omni.ja -appdir /usr/lib/firefox/browser 3591 true tab
learnin+ 4183 3578 0 20:28 pts/0 00:00:00 grep --color=auto firefox
learninglinux@learninglinux-VirtualBox:~$
```

Figure 12.4: Chaining the `ps` and `grep` commands

The output of this command is a trimmed version of the output of the `ps -ef` command. As seen in the before, the `grep` command will return all the lines that contain the given word. And combining these two commands finding the proper process ID simpler.

In the filtering and regular expressions chapter, we ran the `uniq` command to display the unique items in the `randomness.txt` file. However, it was difficult to determine if any repeated items were removed. To determine if any items were repeated in the `randomness.txt` file, we can combine the output of the `uniq` command with the `wc` command. Go to the terminal and type in `uniq randomness.txt | wc`.

```
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io
File Edit View Search Terminal Help
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$ uniq randomness.txt | wc
25 25 218
learninglinux@learninglinux-VirtualBox:~/Documents/learninglinux/io$
```

Figure 12.5: Chaining the `uniq` and `wc` commands

The output of this chain of commands is 25. And since the original file has 25 strings in it, we know that there were no repeated items.

Chapter 13

Basic Networking

Definitions

1. **Hostname** - label assigned to a device connected to a computer network

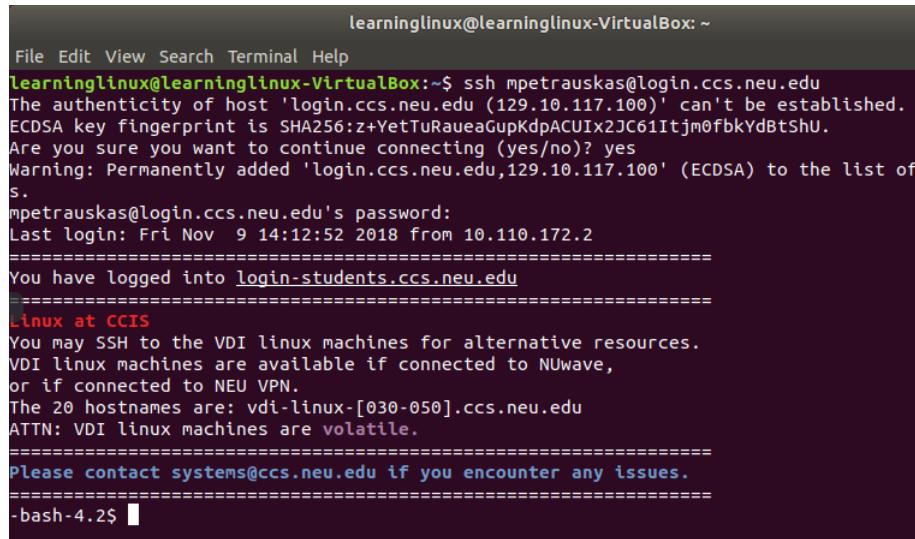

Networking

Networking enables you to connect to, send, and receive information from other machines.

Secure Shell

The most important method of communicating with another computer with the shell is via *secure shell* or **ssh**. The **ssh** command will run the OpenSSH SSH client, which is a remote login program. The syntax for the **ssh** command is **ssh [OPTIONS] [HOSTNAME]**. In general, only the hostname needs to be provided with the **ssh** command, but there are cases where a username is needed. One such example is when you need to login to the CCIS Servers. To login to these servers, you have to use the following format: **ssh username@hostname**. More specifically, for the CCIS Servers, it would be **ssh [your username]@login.ccs.neu.edu**.

Go to the terminal and try to log in to the CCIS Server.

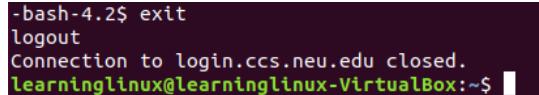

```

learninglinux@learninglinux-VirtualBox: ~
File Edit View Search Terminal Help
learninglinux@loginlinux-VirtualBox:~$ ssh mpetrauskas@login.ccs.neu.edu
The authenticity of host 'login.ccs.neu.edu (129.10.117.100)' can't be established.
ECDSA key fingerprint is SHA256:z+YetTuRaueaGupKdpACUIx2JC61Itjm0fbkYdBtShU.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'login.ccs.neu.edu,129.10.117.100' (ECDSA) to the list of
s.
mpetrauskas@login.ccs.neu.edu's password:
Last login: Fri Nov  9 14:12:52 2018 from 10.110.172.2
=====
You have logged into login-students.ccs.neu.edu
=====
Linux at CCIS
You may SSH to the VDI linux machines for alternative resources.
VDI linux machines are available if connected to NUwave,
or if connected to NEU VPN.
The 20 hostnames are: vdi-linux-[030-050].ccs.neu.edu
ATTN: VDI linux machines are volatile.
=====
Please contact systems@ccs.neu.edu if you encounter any issues.
=====
-bash-4.2$ 

```

Figure 13.1: ssh Command

You will be prompted for a password and once you are connected to the CCIS Server you will be in an entirely new bash shell that is run by the server.

```

-bash-4.2$ exit
logout
Connection to login.ccs.neu.edu closed.
learninglinux@learninglinux-VirtualBox:~$ 

```

Figure 13.2: ssh Exit

Once you are done on the remote server, you can use the **exit** command to close the connection to the CCIS server and return to the shell on your localhost.

Secure Copy

Simply connecting to another machine may not be enough. Often, files need to be transferred between machines. In order to do this, use the **scp command**, which stands for secure copy. The syntax for the **scp** command is **scp [OPTIONS] [LOCALHOST] [REMOTEHOST]**. This command can be used to transfer files from your localhost (your machine) to a remote host (the CCIS Server) or vice versa. It can also be used to transfer files from two remote hosts (e.g. from the CCIS server to another external server).

To transfer a file from the localhost to a remote host, the **scp** command has the following syntax: **scp [FILENAME] [REMOTEHOST FILEPATH]**. To transfer a file, I would type in *scp testing.tar.gz mpetrauskas@login.ccs.neu.edu:/home/mpetrauskas/learninglinux*

```
learninglinux@learninglinux-VirtualBox:~$ scp testing.tar.gz mpetrauskas@login.ccs.neu.edu:/home/mpetrauskas/learninglinux
mpetrauskas@login.ccs.neu.edu's password:
testing.tar.gz                                         100% 175      52.1KB/s   00:00
learninglinux@learninglinux-VirtualBox:~$
```

Figure 13.3: Copying a file to a Remote Server

The file was successfully transferred to the CCIS Server, and we can see the file once we log in into the server.

```
learninglinux@learninglinux-VirtualBox:~$ ssh mpetrauskas@login.ccs.neu.edu
mpetrauskas@login.ccs.neu.edu's password:
Last login: Sun Nov 11 20:36:24 2018 from 10.110.172.2
=====
You have logged into login-students.ccs.neu.edu
=====
Linux at CCIS
You may SSH to the VDI linux machines for alternative resources.
VDI linux machines are available if connected to NUwave,
or if connected to NEU VPN.
The 20 hostnames are: vdi-linux-[030-050].ccs.neu.edu
ATTN: VDI linux machines are volatile.
=====
Please contact systems@ccs.neu.edu if you encounter any issues.
=====
-bash-4.2$ cd learninglinux
-bash-4.2$ ls
testing.tar.gz
-bash-4.2$
```

Figure 13.4: Confirming the file has been transferred

To transfer a file from a remote host to a localhost, the **scp** command has the following syntax: **scp [REMOTEHOST FILEPATH] [LOCALHOST FILEPATH]**. The file will be transferred from the remote host at the given filepath to the filepath on the localhost. To transfer a file, I would type in *scp mpetrauskas@login.ccs.neu.edu:/home/learninglinux/testing2.tar.gz ~*. Note that the “~” at the end of the command indicates the home directory on the virtual machine.

```
learninglinux@learninglinux-VirtualBox:~$ scp mpetrauskas@login.ccs.neu.edu:/home/mpetrauskas/learninglinux/testing2.tar.gz ~
mpetrauskas@login.ccs.neu.edu's password:
testing2.tar.gz                                         100% 193      66.4KB/s   00:00
learninglinux@learninglinux-VirtualBox:~$ ls
Desktop    Downloads    Music      Pictures    Templates    testing.tar.gz
Documents  examples.desktop  myfile.txt  Public      testing2.tar.gz  Videos
learninglinux@learninglinux-VirtualBox:~$
```

Figure 13.5: Copying a file from a Remote Server

It is simple to verify that the file has been successfully transferred back to the localhost. Check your home directory for the file. Now, try this out on some files and move them between your virtual machine and the CCIS Server.

Note: the `scp` command can also transfer entire directories between machines.

Command Summary

Command	Purpose
<code>ssh [HOSTNAME]</code>	remotely connect to the specified HOSTNAME
<code>scp [LOCALHOST] [REMOTEHOST]</code>	copies the file at the LOCALHOST filepath to the REMOTEHOST filepath
<code>scp [REMOTEHOST] [LOCALHOST]</code>	copies the file at the REMOTEHOST filepath to the LOCALHOST filepath
<code>exit</code>	closes the active bash shell

Chapter 14

Command Cheat Sheet

The following is a table of the most important commands covered in this guide and should be used as a reference when the syntax or purpose of a command is needed.

File System Navigation

Command	Purpose
pwd	print name of current/working directory
cd [DIR]	change the working directory to DIR
ls	list directory contents

File Manipulation

Command	Purpose
file [FILENAME]	Determines the file type of FILENAME
mkdir [DIRECTORY]	Make the directory DIRECTORY
cp [SOURCE] [DEST]	Copy the SOURCE TO DEST
rm [FILENAME]	Remove or delete FILENAME
mv [SOURCE] [DIRECTORY]	Move the SOURCE file or directory to DIRECTORY
mv [SOURCE] [DEST]	Rename the SOURCE file or directory to DEST

Process Management

Command	Purpose
ps [OPTIONS]	displays all the active processes
top	displays all the active processes
kill [PID]	kill the process with the given PID
wget [URL]	downloads a file from the URL
jobs	displays the status of all the current jobs
fg	moves the most recent job to the foreground

Filtering

Command	Purpose
head [OPTIONS] [FILE]	return lines from the beginning of the FILE
tail [OPTIONS] [FILE]	return lines from the end of the FILE
sort [OPTIONS] [FILE]	sort the lines of FILE alphabetically
uniq [OPTIONS] [INPUT]	return non-repeating lines from the INPUT
wc [OPTIONS] [FILE]	give the word count of FILE
grep [OPTIONS] PATTERN [FILE]	search for the PATTERN in the lines of FILE

Networking

Command	Purpose
ssh [HOSTNAME]	remotely connect to the specified HOSTNAME
scp [LOCALHOST] [REMOTEHOST]	copies the file at the LOCALHOST filepath to the REMOTEHOST filepath
scp [REMOTEHOST] [LOCALHOST]	copies the file at the REMOTEHOST filepath to the LOCALHOST filepath
exit	closes the active bash shell

Miscellaneous

Command	Purpose
chmod [MODE] [FILE]	change permissions to MODE for FILE
chmod [OCTAL MODE] [FILE]	change permission to OCTAL MODE for FILE
man [COMMAND]	displays the manual page for COMMAND
man -k [KEYWORD]	searchs all the manual pages for the KEYWORD
echo [STRING]	displays the STRING to the standard output
